

SNS COLLEGE OF ALLIED HEALTH SCIENCE
Affiliated to The Tamil Nadu Dr. M.G.R Medical University, Chennai

DEPARTMENT OF RADIOGRAPHY AND IMAGING TECHNOLOGY

COURSE NAME : HUMAN ANATOMY,PHYSIOLOGY AND PATHOLOGY

RELEVANT TO RADIOLOGY

UNIT : GENERAL STRUCTURE OF HUMAN BODY

TOPIC :CELL CYCLE

FACULTY NAME: MRS.G.HELANA JOY

INTRODUCTION (Define)

- **Cell division** is the process in which one cell, called the parent cell, divides to form two new cells, referred to as daughter cells.
- The **cell cycle** is a repeating series of events that include growth, DNA synthesis, and cell division.
- The cell cycle is composed of two major stages: **Interphase and the mitotic (M) phase.**

INTERPHASE

- Interphase is the longest part of the cell cycle, where the **cell grows** and makes a copy of its DNA.
- It is a period of intense metabolic activity and preparation for division and is divided into three substages: **G1 phase** (First Gap), **S phase** (Synthesis), **G2 phase** (Second Gap).

- **G1 phase (First Gap):** The cell grows physically larger, duplicates its organelles (such as mitochondria and ribosomes).
- And synthesizes proteins and molecular building blocks it will need in later steps.

- **S phase (Synthesis):** The cell synthesizes a complete, **identical copy of the DNA** in its nucleus.
- Each chromosome is replicated to produce two identical sister chromatids attached at the centromere.
- The centrosome is also duplicated during this phase.

- **G2 phase (Second Gap):** The cell grows more, produces additional proteins and enzymes required for cell division and reorganizes its contents in preparation for mitosis.
- A final checkpoint ensures the **DNA has been replicated** accurately and is not damaged before entering the M phase.

MITOTIC (M) PHASE

- The M phase is when the cell divides its copied DNA and cytoplasm to **form two new cells**.
- It consists of two tightly coupled processes: Mitosis (Nuclear Division) and Cytokinesis (Cytoplasmic Division)
- **Mitosis (Nuclear Division):** The nuclear DNA is condensed into visible chromosomes and separated into two identical nuclei.

This process is divided into four main stages:

- Prophase
- Metaphase
- Anaphase
- Telophase

- **Prophase:** Chromosomes condense and become visible; the nuclear envelope breaks down; the mitotic spindle begins to form.
- **Metaphase:** Chromosomes align along the center of the cell (the metaphase plate).
- **Anaphase:** Sister chromatids separate and are pulled to opposite ends (poles) of the cell.

Prophase

Metaphase

- **Telophase:** Two new nuclear envelopes form around the two sets of chromosomes, which begin to decondense.
- **Cytokinesis (Cytoplasmic Division):** The cell's cytoplasm divides, forming two separate daughter cells.

Anaphase

Telophase

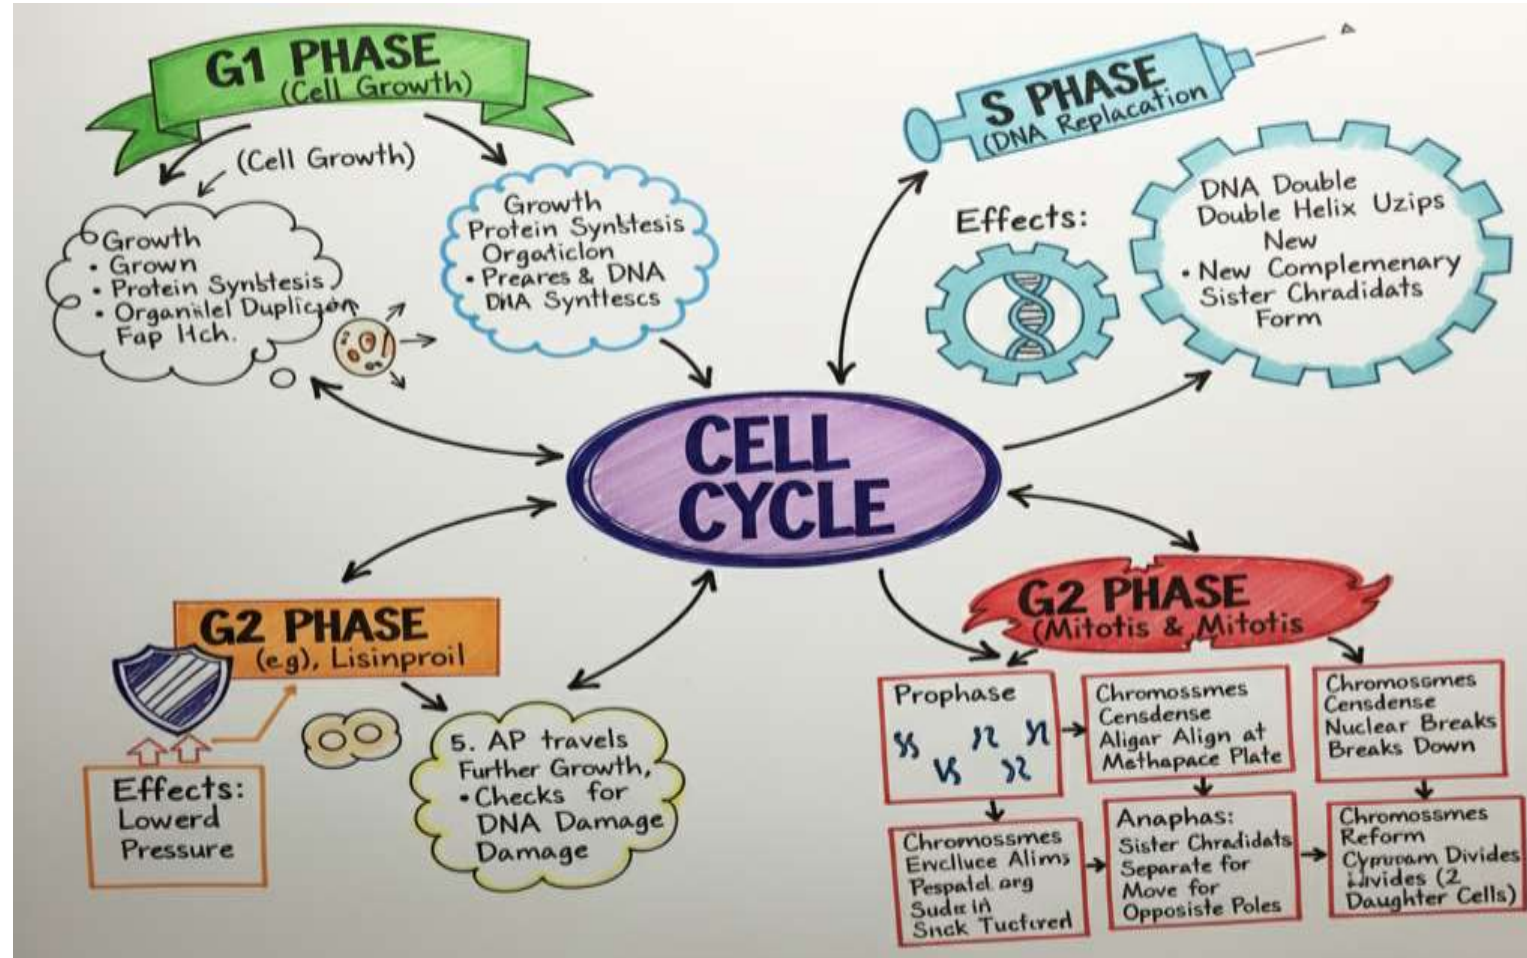

REGULATION AND CHECKPOINTS

- The cell cycle is tightly regulated by a control system with **checkpoints** that monitor progression and ensure all conditions are met before proceeding to the next phase.
- Key regulatory molecules include **cyclins and cyclin-dependent kinases (Cdks)**, whose fluctuating levels and activity drive the cell through the cycle transitions.
