## **Department of Information Technology**

**Course Name – 19IT401 Computer Networks** 

II Year / IV Semester

**Unit 2 – Link Layer** 

**Topic 2- DLC Protocls** 

Traditionally four protocols have been defined for the data-link layer to deal with flow and error control:

- Simple, •
- Stop-and-Wait,
- Go-Back-N, and  $\bullet$
- Selective-Repeat  $\bullet$

Although the first two protocols still are used at the data-link layer, the last two have disappeared.

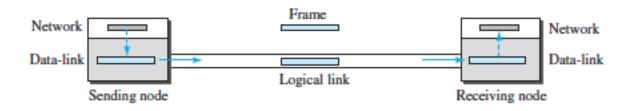

**DLC Protocols/ Computer Networks /IT / SNSCE** 

### Simple Protocol

- Our first protocol is a simple protocol with neither flow nor error control.
- We assume that the receiver can immediately handle any frame it receives. In other words, the receiver can never be overwhelmed with incoming frames.
- The data-link layer at the sender gets a packet from its network layer, makes a frame out of it, and sends the frame.
- The data-link layer at the receiver receives a frame from the link, extracts the packet from the • frame, and delivers the packet to its network layer.
- The data-link layers of the sender and receiver provide transmission services for their network layers.

INSTITUTIONS

### Stop-and-Wait Protocol

- The sender keeps a copy of the frame and then transmits it.
- The sender waits for an acknowledgment before transmitting the next frame.
- If the acknowledgment does not arrive before the sender times out and retransmits the frame.
- In this protocol, the sender sends one frame at a time and waits for an acknowledgment before sending the next one.
- To detect corrupted frames, we need to add a CRC to each data frame.  $\bullet$
- When a frame arrives at the receiver site, it is checked. If its CRC is incorrect, the frame is corrupted and • silently discarded. The silence of the receiver is a signal for the sender that a frame was either corrupted or lost.
- Every time the sender sends a frame, it starts a timer. If an acknowledgment arrives before the timer  $\bullet$ expires, the timer is stopped and the sender sends the next frame.
- If the timer expires, the sender resends the previous frame, assuming that the frame was either lost or corrupted. This means that the sender needs to keep a copy of the frame until its acknowledgment arrives.

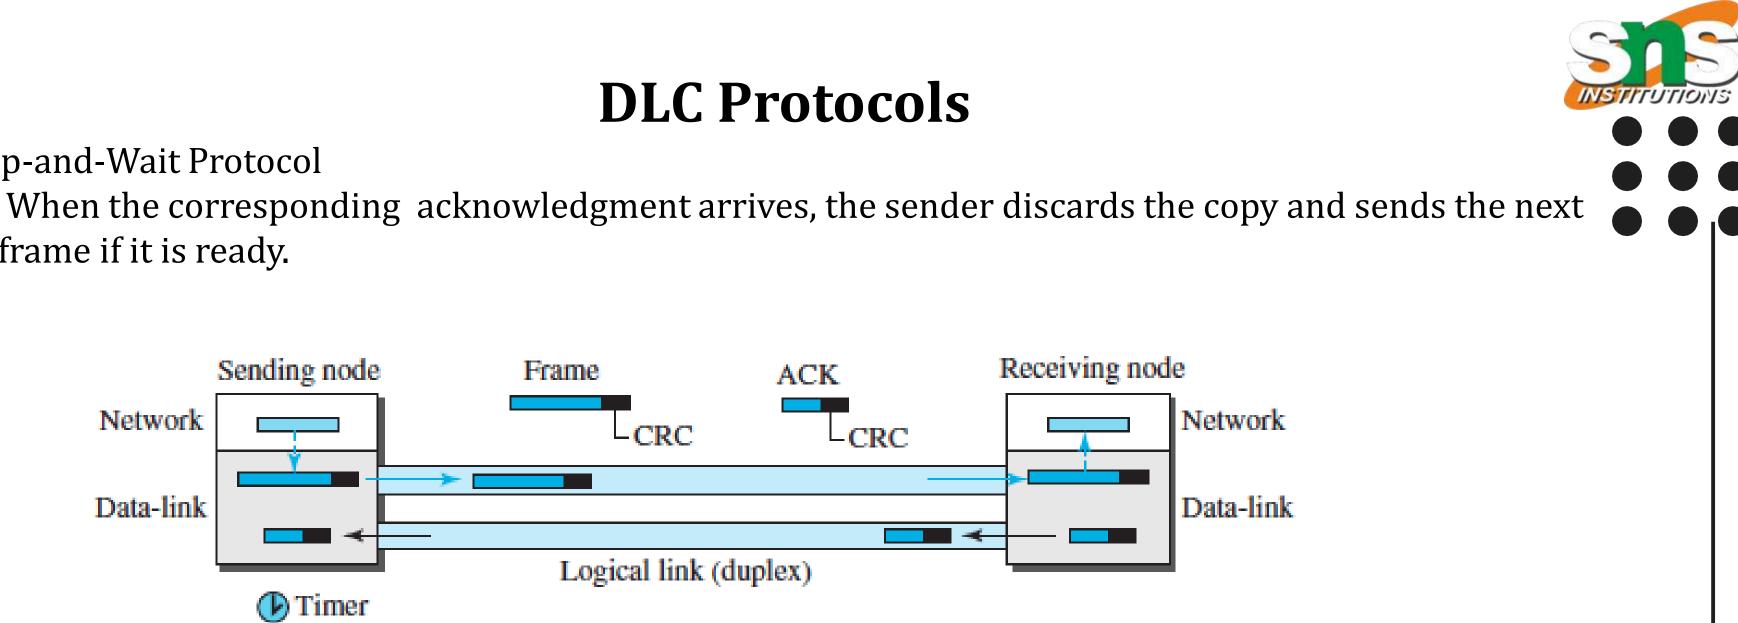

### **DLC Protocols/ Computer Networks /IT / SNSCE**

### Stop-and-Wait Protocol

 $\bullet$ frame if it is ready.

**DLC Protocols/ Computer Networks /IT / SNSCE** 

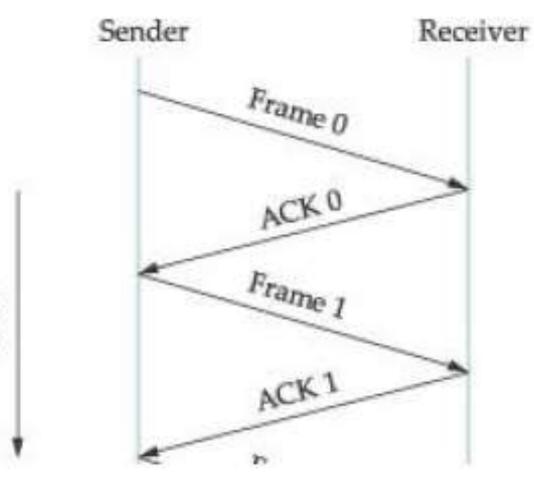

### Stop-and-Wait Protocol

To address duplicate frames, the header for a stop-and-wait protocol includes 1-bit а sequence number (0 or 1)

Go Back N ARQ

- Several frames are sent before receiving acknowledgment. No. of frames that can be sent depends on the size of send window.
- Only one timer is used. When the timer for the first outstanding frame expires, all outstanding frames are resent.
- An acknowledgment number in this protocol is cumulative and defines the sequence number of the  $\bullet$ next packet expected. For example, if the acknowledgment number (ackNo) is 7, it means all packets with sequence number up to 6 have arrived, safe and sound, and the receiver is expecting the packet with sequence number 7.

### Send Window

- The send window is an imaginary box covering the sequence numbers of the data packets that can be in transit or can be sent.
- In each window position, some of these sequence numbers define the packets that have been sent;  $\bullet$ others define those that can be sent. The maximum size of the window is 2m - 1,

### **DLC Protocols/ Computer Networks /IT / SNSCE**

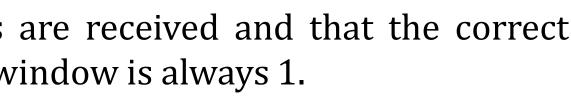

### Go Back N ARQ **Receive Window**

- The receive window makes sure that the correct data packets are received and that the correct acknowledgments are sent. In Go-Back-N, the size of the receive window is always 1.
- The receiver is always looking for the arrival of a specific packet. Any packet arriving out of order is • discarded and needs to be resent.

### Disadvantage

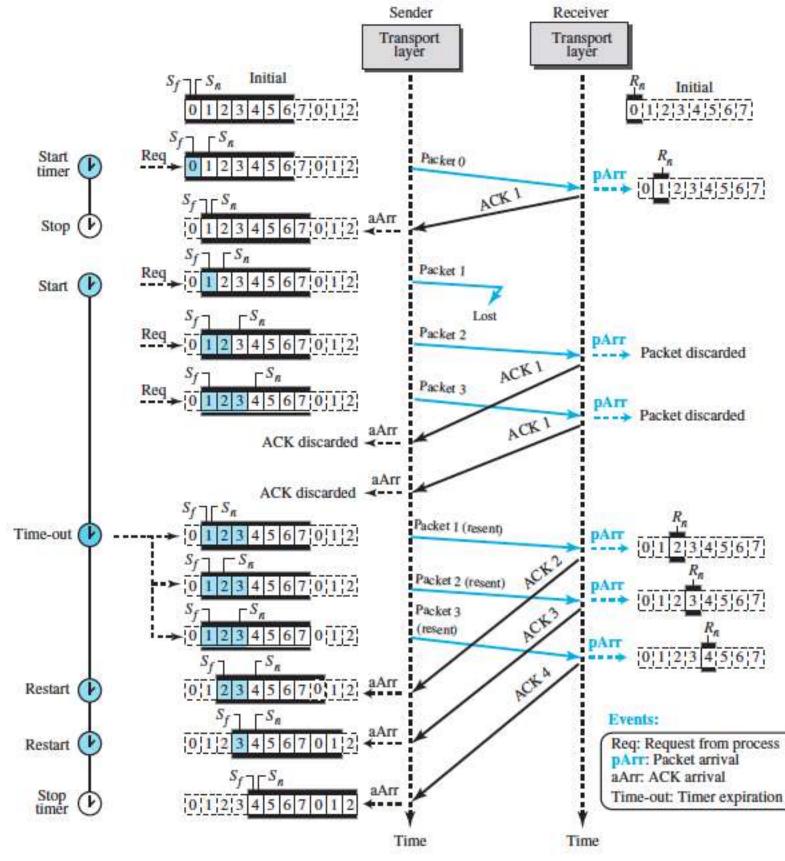

- Each time a single packet is lost or corrupted, the sender resends all outstanding packets, even though some of these packets may have been received safe and sound but out of order.
- If the network layer is losing many packets because of congestion in the network, the resending of all • of these outstanding packets makes the congestion worse, and eventually more packets are lost. This has an avalanche effect that may result in the total collapse of the network.

### Go Back N ARQ

### Selective Repeat ARQ

- Only the damaged/lost frame is resent. This is done by increasing the complexity at the receivers • end.
- The Selective-Repeat protocol also uses two windows: a send window and a receive window. • However, there are differences between the windows in this protocol and the ones in Go-Back-N.
- First, the maximum size of the send window is much smaller; it is 2m-1. Second, the receive window is the same size as the send window.
- The Selective-Repeat protocol allows as many packets as the size of the receive window to arrive out of order and be kept until there is a set of consecutive packets to be delivered to the application layer.
- Theoretically, Selective-Repeat uses one timer for each outstanding packet. When a timer expires, only the corresponding packet is resent
- In SR, an ackNo defines the sequence number of a single packet that is received safe and sound; there is no feedback for any other protocols/ Computer Networks /IT / SNSCE
