

SNS COLLEGE OF ENGINEERING
Kurumbapalayam (Po), Coimbatore – 641 107

An Autonomous Institution

Accredited by NBA – AICTE and Accredited by NAAC – UGC with 'A' Grade
Approved by AICTE, New Delhi & Affiliated to Anna University, Chennai

DEPARTMENT OF CSE

19IT103 – COMPUTATIONAL THINKING AND PYTHON PROGRAMMING

❖ A readable, dynamic, pleasant, flexible, fast and powerful
language

UNIT II DATA TYPES, EXPRESSIONS, STATEMENTS

Python interpreter and interactive mode, debugging; values and types: int, float, boolean, string , and list; variables, expressions, statements, tuple assignment, **precedence of operators**, **comments**; Illustrative programs: exchange the values of two variables, circulate the values of n variables, distance between two points.

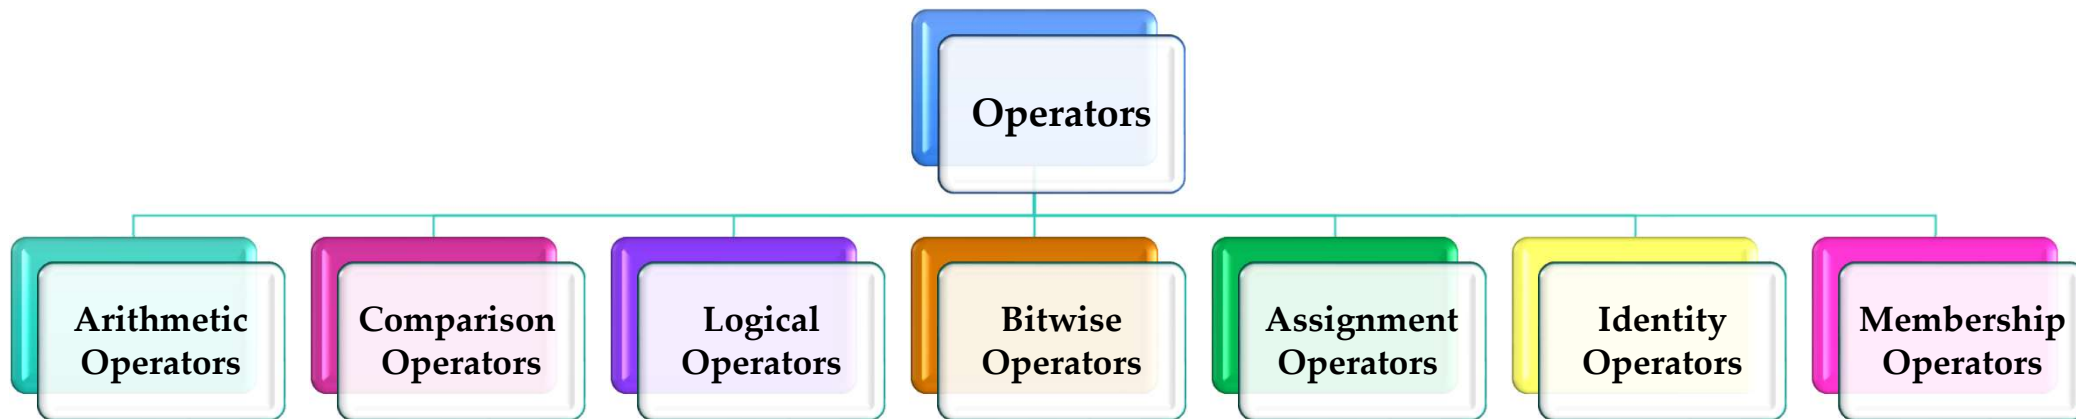

Recap

- Arithmetic Operators
 - Comparison Operators
 - Logical Operators
 - Bitwise Operators
 - Assignment Operators
- 

Operators

- Python Operators in general are used to **perform operations** on **values and variables**.

Identity Operators

- `is` and `is not` are the identity operators both are used to check if two values are located on the same part of the memory.
 - Two variables that are equal do not imply that they are identical.
 - **`is`** True if the operands are identical
 - **`is not`** True if the operands are not identical
- 

Identity Operators

```
>>> num1 = 10
>>> num2 = 20
>>> num1=num2
>>> print(num1 is not num2)
False
>>> print(num1 is num2)
True
>>> |
```

Membership Operators

- **in and not in** are the membership operators; used to test whether a value or variable is in a sequence.
 - **in** True if value is found in the sequence
 - **not in** True if value is not found in the sequence

Example

Precedence and Associativity of Operators

- When dealing with operators in Python we have to know about the concept of Python operator precedence and associativity as these determine the priorities of the operator.
 - **Operator Precedence:** This is used in an expression with more than one operator with different precedence to determine which operation to perform first.
- 

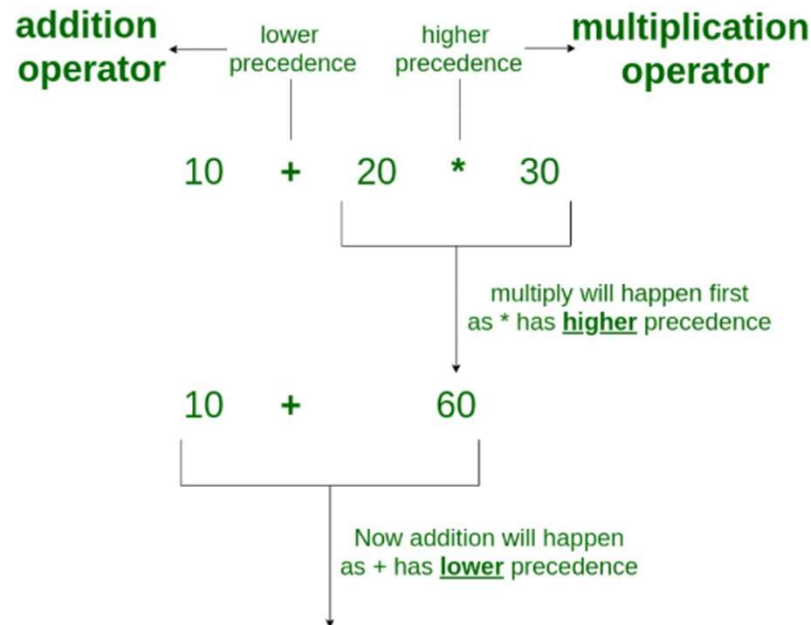

Precedence and Associativity of Operators

- Example: $10 + 20 * 30$
 - Option a: 900
 - Option b: 70
 - Which is correct?
- 

Precedence and Associativity of Operators

- Example: $10 + 20 * 30$

Operator Precedence

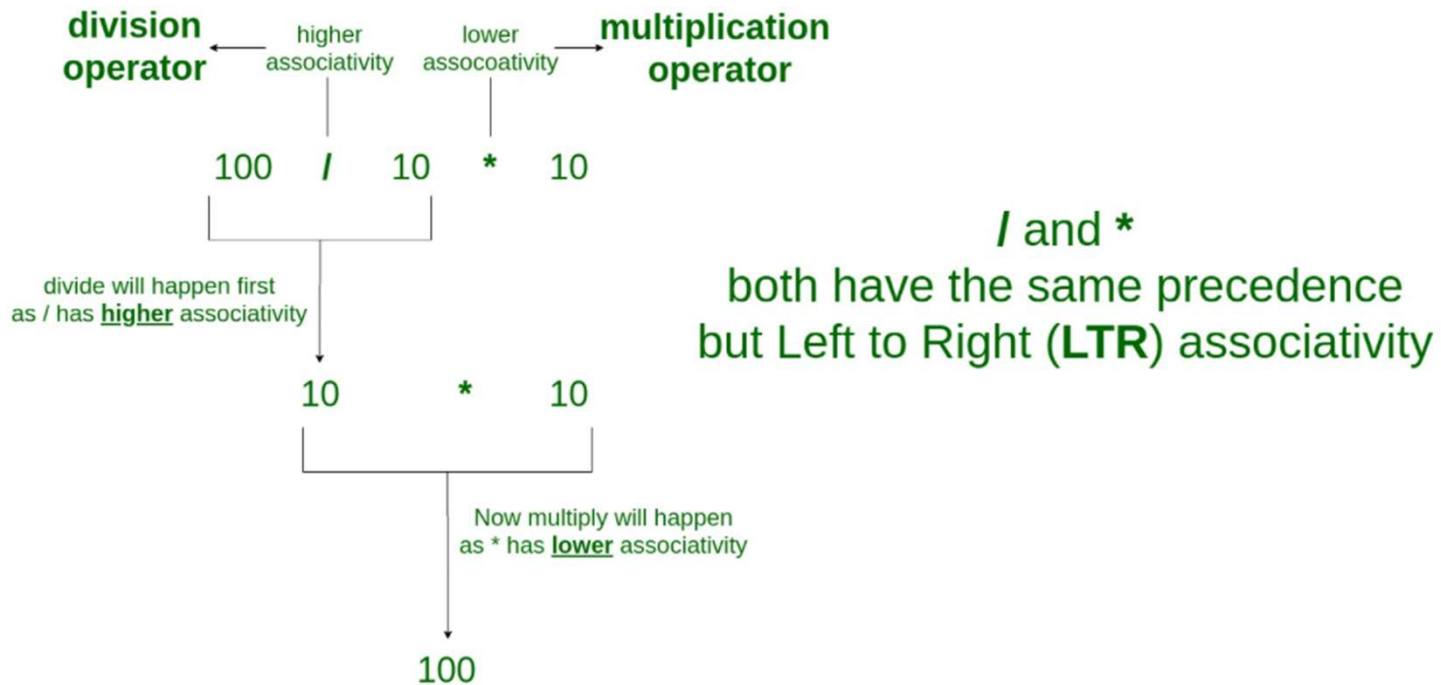

Precedence and Associativity of Operators

- **Operator Associativity:** If an expression contains two or more operators with the same precedence then Operator Associativity is used to determine.
 - It can either be Left to Right or from Right to Left.
 - **Example: ‘*’ and ‘/’ have the same precedence and their associativity is Left to Right**
- 

Precedence and Associativity of Operators

Operator Associativity

Precedence and Associativity of Operators

```
Python 3.8.0 Shell
File Edit Shell Debug Options Window Help
Python 3.8.0 (tags/v3.8.0:fa919fd, Oct 14 2019, 19:37:50) [MSC v.1916 64 bit (AMD64)] on win32
Type "help", "copyright", "credits" or "license ()" for more information.
>>> 100 + 200 / 10 - 3 * 10
90.0
>>>
```

Precedence and Associativity of Operators

Operator	Description	Associativity
()	Parentheses	left-to-right
**	Exponent	right-to-left
* / %	Multiplication/division/modulus	left-to-right
+ -	Addition/subtraction	left-to-right
<< >>	Bitwise shift left, Bitwise shift right	left-to-right
< <= > >=	Relational less than/less than or equal to Relational greater than/greater than or equal to	left-to-right

Precedence and Associativity of Operators

Operator	Description	Associativity
== !=	Relational is equal to/is not equal to	left-to-right
is, is not in, not in	Identity Membership operators	left-to-right
&	Bitwise AND	left-to-right
^	Bitwise exclusive OR	left-to-right
 	Bitwise inclusive OR	left-to-right
not	Logical NOT	right-to-left

Precedence and Associativity of Operators

Operator	Description	Associativity
and	Logical AND	left-to-right
or	Logical OR	left-to-right
= += -= *= /= %= &= ^= = <<= >>=	Assignment Addition/subtraction assignment Multiplication/division assignment Modulus/bitwise AND assignment Bitwise exclusive/inclusive OR assignment Bitwise shift left/right assignment	right-to-left

Comments

- Comments in Python are the lines in the code that are ignored by the compiler during the execution of the program.
 - Comments enhance the readability of the code and help the programmers to understand the code very carefully.
 - There are three types of comments in Python –
 - **Single line Comments**
 - **Multiline Comments**
 - **Docstring Comments**
- 

Single-Line Comments

- Python single line comment starts with the hashtag symbol (#) with no white spaces and lasts till the end of the line.
- If the comment exceeds one line then put a hashtag on the next line and continue the comment.
- Python's single-line comments are proved useful for supplying short explanations for variables, function declarations, and expressions.

Print "GeeksforGeeks !" to console

Multi-Line Comments

- Python does not provide the option for multiline comments.
- However, there are different ways through which we can write multiline comments.
- **Using Multiple Hashtags (#)**

Python program to demonstrate

multiline comments

Multi-Line Comments

- Using String Literals

```
""" Python program to demonstrate  
multiline comments """
```

Python Docstring

- Python docstring is the string literals with triple quotes that are appeared right after the function.
 - It is used to associate documentation that has been written with Python modules, functions, classes, and methods.
 - It is added right below the functions, modules, or classes to describe what they do.
 - In Python, the docstring is then made available via the `__doc__` attribute.
- 
- 

Python Docstring

Example
