Probability for machine learning

## Axioms of Probability

Axioms ensure that the probabilities assigned in a random experiment can be interpreted as relative frequencies and that the assignments are consistent with our intuitive understanding of relationships among relative frequencies:

1. $0 \leq \mathrm{P}(\mathrm{E}) \leq 1$. If E 1 is an event that cannot possibly occur, then $\mathrm{P}(\mathrm{E} 1)=0$. If E 2 is sure to occur, $\mathrm{P}(\mathrm{E} 2)=1$.
2. $S$ is the sample space containing all possible outcomes, $P(S)=1$.
3. If $\mathrm{Ei}, \mathrm{i}=1, \ldots, \mathrm{n}$ are mutually exclusive (i.e., if they cannot occur at the same time, as in $\mathrm{Ei} \cap$ $E j=\emptyset_{, j=i}$, where $\emptyset_{\text {is the null event that does not contain any possible outcomes), we have }}$

$$
P\left(\bigcup_{i=1}^{n} E_{i}\right)=\sum_{i=1}^{n} P\left(E_{i}\right)
$$

For example, letting Ec denote the complement of E, consisting of all possible outcomes in S that are not in E , we have $\mathrm{E} \cap \mathrm{EC}=\emptyset$ and

$$
\begin{gathered}
P\left(E \cup E^{c}\right)=P(E)+P\left(E^{c}\right) \\
P\left(E^{c}\right)=1-P(E)
\end{gathered}
$$

If the intersection of E and F is not empty, we have

$$
P(E \cup F)=P(E)+P(F)-P
$$

## Conditional Probability

$\mathrm{P}(\mathrm{E} \mid \mathrm{F})$ is the probability of the occurrence of event E given that F occurred and is given as

SNS COLLEGE OF TECHNOLOGY, COIMBATORE -35
(An Autonomous Institution)
DEPARTMENT OF COMPUTER SCIENCE AND ENGINEERING

$$
P(E \mid F)=\frac{P(E \cap F)}{P(F)}
$$

Knowing that F occurred reduces the sample space to F, and the part of it where E also occurred is $\mathrm{E} \cap \mathrm{F}$. Note that equation is well-defined only if $\mathrm{P}(\mathrm{F})>0$. Because $\cap$ is commutative, we have

$$
P(E \cap F)=P(E \mid F) P(F)=P(F \mid E) P(E)
$$

which gives us Bayes' formula:

$$
P(F \mid E)=\frac{P(E \mid F) P(F)}{P(E)}
$$

When Fi are mutually exclusive and exhaustive,

$$
\begin{aligned}
E & =\bigcup_{i=1}^{n} E \cap F_{i} \\
P(E) & =\sum_{i=1}^{n} P\left(E \cap F_{i}\right)=\sum_{i=1}^{n} P\left(E \mid F_{i}\right) P\left(F_{i}\right)
\end{aligned}
$$

Bayes' formula allows us to write

$$
P\left(F_{i} \mid E\right)=\frac{P\left(E \cap F_{i}\right)}{P(E)}=\frac{P\left(E \mid F_{i}\right) P\left(F_{i}\right)}{\sum_{j} P\left(E \mid F_{j}\right) P\left(F_{j}\right)}
$$

If E and F are independent, we have $\mathrm{P}(\mathrm{E} \mid \mathrm{F})=\mathrm{P}(\mathrm{E})$ and thus

$$
P(E \cap F)=P(E) P(F)
$$

That is, knowledge of whether F has occurred does not change the probability that E occurs.

## DEPARTMENT OF COMPUTER SCIENCE AND ENGINEERING

## Random Variables

A random variable is a function that assigns a number to each outcome in the sample space of a random experiment.

## Probability Distribution and Density Functions

The probability distribution function $\mathrm{F}(\cdot)$ of a random variable X for any real number a is $\mathrm{F}(\mathrm{a})=\mathrm{P}\{\mathrm{X} \leq \mathrm{a}\}$ and we have
$\mathrm{P}\{\mathrm{a}<\mathrm{X} \leq \mathrm{b}\}=\mathrm{F}(\mathrm{b})-\mathrm{F}(\mathrm{a})$

If X is a discrete random variable

$$
F(a)=\sum_{\forall x \leq a} P(x)
$$

where $P(\cdot)$ is the probability mass function defined as $P(a)=P\{X=a\}$. If $X$ is a continuous random variable, $\mathrm{p}(\cdot)$ is the probability density function such that

$$
F(a)=\int_{-\infty}^{a} p(x) d x
$$

## Joint Distribution and Density Functions

In certain experiments, we may be interested in the relationship between two or more random variables, and we use the joint probability distribution and density functions of X and Y satisfying
$\mathrm{F}(\mathrm{x}, \mathrm{y})=\mathrm{P}\{\mathrm{X} \leq \mathrm{x}, \mathrm{Y} \leq \mathrm{y}\}$

Individual marginal distributions and densities can be computed by marginalizing, namely, summing over the free variable:
$\mathrm{FX}(\mathrm{x})=\mathrm{P}\{\mathrm{X} \leq \mathrm{x}\}=\mathrm{P}\{\mathrm{X} \leq \mathrm{x}, \mathrm{Y} \leq \infty\}=\mathrm{F}(\mathrm{x}, \infty)$
In the discrete case, we write

$$
P(X=x)=\sum_{i} P\left(x, y_{j}\right)
$$

SNS COLLEGE OF TECHNOLOGY, COIMBATORE -35
(An Autonomous Institution)

## DEPARTMENT OF COMPUTER SCIENCE AND ENGINEERING

and in the
These can be generalized in a straightforward manner to more than two random variables.

## Conditional Distributions

When X and Y are random variables

$$
P_{X \mid Y}(x \mid y)=P\{X=x \mid Y=y\}=\frac{P\{X=x, Y=y\}}{P\{Y=y\}}=\frac{P(x, y)}{P_{Y}(y)}
$$

## Bayes' Rule

When two random variables are jointly distributed with the value of one known, the probability that the other takes a given value can be computed using Bayes' rule:

$$
P(y \mid x)=\frac{P(x \mid y) P_{Y}(y)}{P_{X}(x)}=\frac{P(x \mid y) P_{Y}(y)}{\sum_{y} P(x \mid y) P_{Y}(y)}
$$

Or, in words

## posterior $=\frac{\text { likelihood } \times \text { prior }}{\text { evidence }}$

## Expectation

Expectation, expected value, or mean of a random variable X , denoted by $\mathrm{E}[\mathrm{X}]$, is the average value of X in a large number of experiments:

$$
E[X]= \begin{cases}\sum_{i} x_{i} P\left(x_{i}\right) & \text { if } X \text { is discrete } \\ \int x p(x) d x & \text { if } X \text { is continuous }\end{cases}
$$

It is a weighted average where each value is weighted by the probability that X takes that value. It has the following properties $(a, b \in \mathfrak{R})$

$$
\begin{aligned}
& \mathrm{E}[\mathrm{aX}+\mathrm{b}]=\mathrm{aE}[\mathrm{X}]+\mathrm{b} \\
& \mathrm{E}[\mathrm{X}+\mathrm{Y}]=\mathrm{E}[\mathrm{X}]+\mathrm{E}[\mathrm{Y}
\end{aligned}
$$

For any real-valued function $g(\cdot)$, the expected value is ${ }^{1}$

## DEPARTMENT OF COMPUTER SCIENCE AND ENGINEERING

$$
E[g(X)]= \begin{cases}\sum_{i} g\left(x_{i}\right) P\left(x_{i}\right) & \text { if } X \text { is discrete } \\ \int g(x) p(x) d x & \text { if } X \text { is continuous }\end{cases}
$$

A special $g(x)=x^{\wedge} n$, called the nth moment of $X$, is defined as

$$
E\left[X^{n}\right]= \begin{cases}\sum_{i} x_{i}^{n} P\left(x_{i}\right) & \text { if } X \text { is discrete } \\ \int x^{n} p(x) d x & \text { if } X \text { is continuous }\end{cases}
$$

Mean is the first moment and is denoted by $\mu$

## Variance

Variance measures how much X varies around the expected value. If $\mu \equiv \mathrm{E}[\mathrm{X}]$, the variance is defined as

$$
\operatorname{Var}(\mathrm{X})=\mathrm{E}[(\mathrm{X}-\mu) 2]=\mathrm{E}[\mathrm{X} 2]-\mu 2
$$

Variance is the second moment minus the square of the first moment. Variance, denoted by $\sigma 2$, satisfies the following property $(\mathrm{a}, \mathrm{b} \in \mathfrak{R}): \operatorname{Var}(\mathrm{aX}+\mathrm{b})=\mathrm{a} 2 \operatorname{Var}(\mathrm{X})$
$\operatorname{Cov}(\mathrm{X}, \mathrm{Y})=\mathrm{E}[(\mathrm{X}-\mu \mathrm{X})(\mathrm{Y}$
$-\mu \mathrm{Y})]=\mathrm{E}[\mathrm{XY}]-\mu \mathrm{X} \mu \mathrm{Y}$
where $\mu \mathrm{X} \equiv \mathrm{E}[\mathrm{X}]$ and $\mu \mathrm{Y} \equiv$
$\mathrm{E}[\mathrm{Y}]$. Some other properties
are
$\operatorname{Cov}(\mathrm{X}, \mathrm{Y})=\operatorname{Cov}(\mathrm{Y}, \mathrm{X})$
$\operatorname{Cov}(\mathrm{X}, \mathrm{X})=\operatorname{Var}(\mathrm{X})$
$\operatorname{Cov}(\mathrm{X}+\mathrm{Z}, \mathrm{Y})=\operatorname{Cov}(\mathrm{X}, \mathrm{Y})+\operatorname{Cov}(\mathrm{Z}, \mathrm{Y})$

$$
\begin{aligned}
& \operatorname{Cov}\left(\sum_{i} X_{i}, Y\right)=\sum_{i} \operatorname{Cov}\left(X_{i}, Y\right) \\
& \operatorname{Var}(X+Y)=\operatorname{Var}(X)+\operatorname{Var}(Y)+2 \operatorname{Cov}(X, Y) \\
& \operatorname{Var}\left(\sum_{i} X_{i}\right)=\sum_{i} \operatorname{Var}\left(X_{i}\right)+\sum_{i} \sum_{j \neq i} \operatorname{Cov}\left(X_{i}, X_{j}\right)
\end{aligned}
$$

If X and Y are independent, $\mathrm{E}[\mathrm{XY}]=\mathrm{E}[\mathrm{X}] \mathrm{E}[\mathrm{Y}]=\mu \mathrm{X} \mu \mathrm{Y}$ and $\operatorname{Cov}(\mathrm{X}, \mathrm{Y})=0$. Thus if Xi are independent

## DEPARTMENT OF COMPUTER SCIENCE AND ENGINEERING

$$
\operatorname{Var}\left(\sum_{i} X_{i}\right)=\sum_{i} \operatorname{Var}\left(X_{i}\right)
$$

Correlation is a normalized, dimensionless quantity that is always between -1 and 1 :

$$
\operatorname{Corr}(X, Y)=\frac{\operatorname{Cov}(X, Y)}{\sqrt{\operatorname{Var}(X) \operatorname{Var}(Y)}}
$$

## Weak Law of Large Numbers

Let $\mathrm{X}=\{\mathrm{Xt}\} \mathrm{Nt}=1$ be a set of independent and identically distributed (iid) random variables each having to mean $\mu$ and a finite variance $\sigma^{\wedge} 2$. Then for any $q>0$

$$
P\left\{\left|\frac{\sum_{t} X^{t}}{N}-\mu\right|>\epsilon\right\} \rightarrow 0 \text { as } N \rightarrow \infty
$$

That is, the average of N trials converge to the mean as N increases.

## Special Random Variables

## Bernoulli Distribution

A trial is performed whose outcome is either a "success" or a "failure." The random variable X is a $0 / 1$ indicator variable and takes the value 1 for a successful outcome and is 0 otherwise. P is the probability that the result of trial the is a success. Then $\mathrm{P}\{\mathrm{X}=1\}=\mathrm{p}$ and $\mathrm{P}\{\mathrm{X}=0\}=$ $1-\mathrm{p}$ which can equivalently be written as

$$
P\{X=i\}=p i(1-p) 1-i, i=0,1
$$

If X is Bernoulli, its expected value and variance are

$$
\mathrm{E}[\mathrm{X}]=\mathrm{p}, \operatorname{Var}(\mathrm{X})=\mathrm{p}(1-\mathrm{p})
$$

## Binomial Distribution

If N identical independent Bernoulli trials are made, the random variable X that represents the number of successes that occurs in N trials is binomial distributed. The probability that there are i successes is

$$
P\{X=i\}=\binom{N}{i} p^{i}(1-p)^{N-i}, i=0 \ldots N
$$

SNS COLLEGE OF TECHNOLOGY, COIMBATORE -35
(An Autonomous Institution)

## DEPARTMENT OF COMPUTER SCIENCE AND ENGINEERING

If X is binomial, its expected value and variance are
$E[X]=N p, \operatorname{Var}(X)=N p(1-p)$

## Multinomial Distribution

Consider a generalization of Bernoulli where instead of two states, the outcome of a random event is one of K mutually exclusive and exhaustive states

$$
P\left(N_{1}, N_{2}, \ldots, N_{K}\right)=N!\prod_{i=1}^{K} \frac{p_{i}^{N_{i}}}{N_{i}!}
$$

A special case is when $\mathrm{N}=1$; only one trial is made. Then Ni is a $0 / 1$ indicator variable of which only one of them is 1 and all others are 0 .

$$
P\left(N_{1}, N_{2}, \ldots, N_{K}\right)=\prod_{i=1}^{K} p_{i}^{N_{i}}
$$

## Uniform Distribution

X is uniformly distributed over the interval $[\mathrm{a}, \mathrm{b}]$ if its density function is given by

$$
p(x)= \begin{cases}\frac{1}{b-a} & \text { if } a \leq x \leq b \\ 0 & \text { otherwise }\end{cases}
$$

If X is uniform, its expected value and variance are

$$
E[X]=\frac{a+b}{2}, \operatorname{Var}(X)=\frac{(b-a)^{2}}{12}
$$

## Normal (Gaussian) Distribution

## DEPARTMENT OF COMPUTER SCIENCE AND ENGINEERING

X is normal or Gaussian distributed with mean $\mu$ and variance $\sigma 2$ denoted as $\mathrm{N}(\mu, \sigma 2)$ if its density function is

If $\mathrm{X} \sim \mathbf{N}(\mu, \sigma 2)$ and Y

$$
\begin{gathered}
p(x)=\frac{1}{\sqrt{2 \pi} \sigma} \exp \left[-\frac{(x-\mu)^{2}}{2 \sigma^{2}}\right],-\infty<x<\infty \\
p_{Z}(x)=\frac{1}{\sqrt{2 \pi}} \exp \left[-\frac{x^{2}}{2}\right]
\end{gathered}
$$

$$
=\quad a X+b, \text { then } Y
$$

$\mathrm{N}(\mathrm{a} \mu+\mathrm{b}, \mathrm{a} 2 \sigma 2)$. The sum of independent normal variables is also normal with $\mu=\mathrm{i} \mu \mathrm{i}$ and $\sigma 2=\mathrm{i} \sigma \mathrm{i}_{2}$. If X is $\mathrm{N}(\mu, \sigma 2)$, then

$$
\frac{X-\mu}{\sigma} \sim Z
$$

This is called z-normalization.

$$
\mathbf{C}
$$

hi-Square Distribution If Zi are
independent unit normal random
variables, then

$$
X=Z_{1}^{2}+Z_{2}^{2}+\ldots+Z_{n}^{2}
$$

is chi-square with $n$ degrees of freedom, namely, $X \sim X 2_{n}$, with $E[X]=n, \operatorname{Var}(X)=2 n$ When $X t \sim$ $\mathrm{N}(\mu, \sigma 2)$, the estimated sample variance is

SNS COLLEGE OF TECHNOLOGY, COIMBATORE -35
(An Autonomous Institution)
DEPARTMENT OF COMPUTER SCIENCE AND ENGINEERING

$$
\begin{array}{r}
S^{2}=\frac{\sum_{t}\left(X^{t}-m\right)^{2}}{N-1} \\
\quad(N-1) \frac{S^{2}}{\sigma^{2}} \sim X_{N-1}^{2}
\end{array}
$$

and we have

It is also known that m and S 2 are independent.

Distribution If Z~Z
and $\mathrm{X} \sim \mathrm{X}^{\wedge} 2 \mathrm{n}$ are
independent, then

$$
T_{n}=\frac{Z}{\sqrt{X / n}}
$$

is t -distributed with n degrees of freedom with

$$
E\left[T_{n}\right]=0, n>1, \operatorname{Var}\left(T_{n}\right)=\frac{n}{n-2}, n>2
$$

## F Distribution

If $\mathrm{X} 1 \sim \mathrm{X} 2 \mathrm{n}$ and $\mathrm{X} 2 \sim \mathrm{X} 2 \mathrm{~m}$ are independent chi-square random variables with n and m degrees of freedom respectively,

$$
F_{n, m}=\frac{X_{1} / n}{X_{2} / m}
$$

is F -distributed with n
and $m$ degrees of
freedom with

SNS COLLEGE OF TECHNOLOGY, COIMBATORE -35 (An Autonomous Institution)

DEPARTMENT OF COMPUTER SCIENCE AND ENGINEERING

$$
E\left[F_{n, m}\right]=\frac{m}{m-2}, m>2, \operatorname{Var}\left(F_{n, m}\right)=\frac{m^{2}(2 m+2 n-4)}{n(m-2)^{2}(m-4)}, m>4
$$
