

# Sensors and Actuators with Arduino

Hans-Petter Halvorsen, M.Sc.

# System Overview

```
AnalogInput 5  
  
int sensorPin = A0; // select the input pin for the potentiometer  
int ledPin = 13; // select the pin for the LED  
int sensorValue = 0; // variable to store the value coming from the sensor  
  
void setup() {  
  // declare the ledPin as an OUTPUT:  
  pinMode(ledPin, OUTPUT);  
}  
  
void loop() {  
  // read the value from the sensor:  
  sensorValue = analogRead(sensorPin);  
  // turn the ledPin on  
  digitalWrite(ledPin, HIGH);  
  // stop the program for <sensorValue> milliseconds:  
  delay(sensorValue);  
  // turn the ledPin off:  
  digitalWrite(ledPin, LOW);  
  // stop the program for for <sensorValue> milliseconds:  
  delay(sensorValue);  
}
```

# Lab Topics

- Get Overview of the Arduino Platform
- Sensors and Actuators Overview in general
- Overview of Temperature Sensors, such as
  - Pt-100, Thermistor, Thermocouple
- Basic Data Acquisition (DAQ), Data Logging
- Calibration, Uncertainty, Resolution, Accuracy, Range, etc.
- Lowpass Filter implementation in Software
- Network Communication
- Reading Data sheets

# Assignment Overview

1. Arduino Basics: Explore the different Sensors and Actuators available with the Arduino Kit
2. Temperature Sensors
3. Pt-100: Create your own Pt-100 sensor with Transmitter from scratch and Read Temperature values using Arduino
4. Create a Temperature Data Logger/Embedded DAQ System. Select one of the following alternatives:
  - a) Save Data using SD Card available on Arduino Shields
  - b) Use an online web-based Data Logging Service like Temboo/Xively
  - c) Use Wireless Communication to your PC using XBee Modules

See next slides for details...

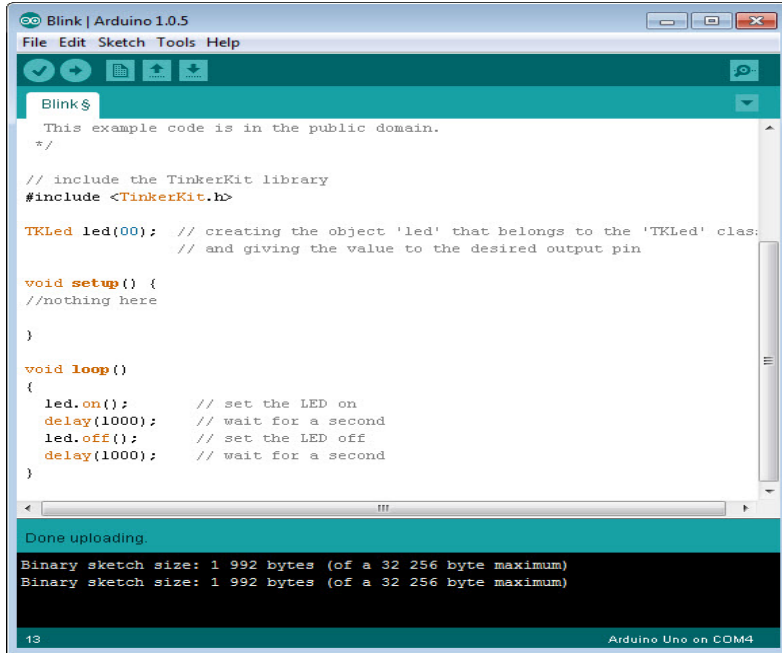

# Arduino

# Software

Programming with Arduino is simple and intuitive!

## Arduino Sketch IDE

```
Blink | Arduino 1.0.5
File Edit Sketch Tools Help
Blink $
This example code is in the public domain.
*/
// include the TinkerKit library
#include <TinkerKit.h>
TKLed led(00); // creating the object 'led' that belongs to the 'TKLed' class
// and giving the value to the desired output pin
void setup() {
//nothing here
}
void loop()
{
led.on(); // set the LED on
delay(1000); // wait for a second
led.off(); // set the LED off
delay(1000); // wait for a second
}
Done uploading.
Binary sketch size: 1 992 bytes (of a 32 256 byte maximum)
Binary sketch size: 1 992 bytes (of a 32 256 byte maximum)
13 Arduino Uno on COM4
```

The syntax is similar to C programming

## Example:

```
// include the TinkerKit library
#include <TinkerKit.h>
// creating the object 'led' that belongs to the 'TKLed' class
TKLed led(00);
void setup()
{
//do something here
}
void loop()
{
led.on(); // set the LED on
delay(1000); // wait for a second
led.off(); // set the LED off
delay(1000); // wait for a second
}
```

This program makes a LED blink

# Sensors and Actuators

- A **Sensor** is a converter that measures a physical quantity and converts it into a signal which can be read by an observer or by an (today mostly electronic) instrument.
- An **Actuator** is a type of motor for moving or controlling a mechanism or system. It is operated by a source of energy, typically electric current, hydraulic fluid pressure, or pneumatic pressure, and converts that energy into motion. An actuator is the mechanism by which a control system acts upon an environment.

<http://en.wikipedia.org/wiki/Sensor>

<http://en.wikipedia.org/wiki/Actuator>

# Sensors

**Calibration:** A comparison between measurements. One of known magnitude or correctness made or set with one device and another measurement made in as similar a way as possible with a second device. The device with the known or assigned correctness is called the standard. The second device is the unit under test, test instrument, or any of several other names for the device being calibrated.

**Resolution:** The smallest change it can detect in the quantity that it is measuring. The following formula may be used (where  $S$  is the measurement span, e.g., 0-100deg.C):

$$R = \frac{S}{2^n - 1}$$

In the assignment you need to deal with these parameters. You find information about these parameters in the Data sheet for your device

<http://en.wikipedia.org/wiki/Calibration>

[http://en.wikipedia.org/wiki/Measurement\\_uncertainty](http://en.wikipedia.org/wiki/Measurement_uncertainty)

[http://en.wikipedia.org/wiki/Accuracy\\_and\\_precision](http://en.wikipedia.org/wiki/Accuracy_and_precision)

**Accuracy:** How close the measured value is to the actual/real value, e.g.,  $\pm 0.1\%$

# Arduino Basics

## Getting Started with Arduino

Hans-Petter Halvorsen, M.Sc.

- Arduino is an open-source physical computing platform designed to make experimenting with electronics and programming more fun and intuitive.
- Arduino has its own unique, simplified programming language and a lots of premade examles and tutorials exists.
- With Arduino you can easily explore lots of small-scale sensors and actuators like motors, temperature sensors, etc.
- The possibilities with Arduino are endless.

Pin Overview: <http://pighixx.com/unov3pdf.pdf>

# The Arduino Programming Environment (IDE)

The Arduino Integrated Development Environment - or Arduino Software (IDE) - contains a text editor for writing code, a message area, a text console, a toolbar with buttons for common functions and a series of menus. It connects to the Arduino hardware to upload programs and communicate with them.

The screenshot shows the Arduino IDE interface. The title bar reads "Blink | Arduino 1.6.5". The main text area contains the following code:

```
Blink

pin the on-board LED is connected to on your Arduino model, check
the documentation at http://www.arduino.cc

This example code is in the public domain.

modified 8 May 2014
by Scott Fitzgerald
*/

// the setup function runs once when you press reset or power the board
void setup() {
  // initialize digital pin 13 as an output.
  pinMode(13, OUTPUT);
}

// the loop function runs over and over again forever
void loop() {
  digitalWrite(13, HIGH); // turn the LED on (HIGH is the voltage level)
  delay(1000);           // wait for a second
  digitalWrite(13, LOW);  // turn the LED off by making the voltage LOW
  delay(1000);           // wait for a second
}
```

Below the code editor, a console window shows the output of the upload process:

```
Done uploading.
32,256 bytes.
Global variables use 9 bytes (0%) of dynamic memory, leaving 2,039
bytes for local variables. Maximum is 2,048 bytes.
```

The status bar at the bottom indicates "Arduino Uno on /dev/cu.usbmodem1411".

Arduino Uno Board

# Arduino Basics

Breadboard

Sensors and Actuators

# The Arduino Kit

Small-size Sensors and Actuators

Getting Started with Arduino: <http://arduino.cc/en/Guide/HomePage>

# Getting Started

- Arduino with Breadboard Sensors/Actuators:
  - LED
  - Push Button
  - Potentiometer
  - Different Temperature Sensors
  - etc.
- Install the Arduino Sketch and Explore some of these Sensors & Actuators, i.e., make 2-3 Examples.
- Use the breadboard for creating your circuits.
- Use Arduino Sketch in order to create the Programs that interface with the Sensors & Actuators

Congratulations! - You are finished with the Task

# Temperature Sensors

Hans-Petter Halvorsen, M.Sc.

# Temperature Measurements

Different methods for measuring the Temperature:

- Thermocouples
- Thermistors
- RTD (Resistance Temperature Detector)
  - e.g. Pt100
- Infrared
- Thermometers

# TMP36

- These sensors use a solid-state technique to determine the temperature. That is to say, they don't use mercury (like old thermometers), bimetallic strips (like in some home thermometers or stoves), nor do they use thermistors (temperature sensitive resistors).
- Instead, they use the fact as temperature increases, the voltage across a diode increases at a known rate. (Technically, this is actually the voltage drop between the base and emitter - the  $V_{be}$  - of a transistor.)
- By precisely amplifying the voltage change, it is easy to generate an analog signal that is directly proportional to temperature. There have been some improvements on the technique but, essentially that is how temperature is measured.

Because these sensors have no moving parts, they are precise, never wear out, don't need calibration, work under many environmental conditions, and are consistent between sensors and readings. Moreover they are very inexpensive and quite easy to use.

# Datasheet Calculations

Figure 6. Output Voltage vs. Temperature

You have to find a (slope) and b (intercept):

$$y - 25^{\circ}\text{C} = ((50^{\circ}\text{C} - 25^{\circ}\text{C}) / (1000\text{mV} - 750\text{mV})) * (x - 750\text{mV})$$

This gives:  $y[^{\circ}\text{C}] = (1/10) * x[\text{mv}] - 50$

From the plot we have:

$$(x_1, y_1) = (750\text{mV}, 25^{\circ}\text{C})$$

$$(x_2, y_2) = (1000\text{mV}, 50^{\circ}\text{C})$$

Linear relationship:  $y = ax + b$

$$y - y_1 = \frac{y_2 - y_1}{x_2 - x_1} (x - x_1)$$

# Voltage-based Sensors

TMP36

According to the TMP36 datasheet, the relation of the output voltage to the actual temperature uses this equation:

$$y[^\circ\text{C}] = (1/10) * x[\text{mv}] - 50$$

Where the voltage value is specified in millivolts.

However, before you use that equation, you must convert the integer value that the analogRead function returns into a millivolt value.

10-bit analog to digital converter

You know that for a 5000mV (5V) value span the analogRead function will return 1024 possible values:

$$\text{voltage} = (5000 / 1024) * \text{output}$$

mV

Where

$$\text{output} = \text{analogRead}(\text{aichannel})$$

0-1023

A0-A5

# TMP36 Temperature Sensor Example

```
// We'll use analog input 0 to read Temperature Data

const int temperaturePin = 0;

void setup()
{
  Serial.begin(9600);
}

void loop()
{
  float voltage, degreesC, degreesF;

  voltage = getVoltage(temperaturePin);

  // Now we'll convert the voltage to degrees Celsius.
  // This formula comes from the temperature sensor datasheet:

  degreesC = (voltage - 0.5) * 100.0;

  // Send data from the Arduino to the serial monitor window
  Serial.print("voltage: ");
  Serial.print(voltage);
  Serial.print(" deg C: ");
  Serial.println(degreesC);

  delay(1000); // repeat once per second (change as you wish!)
}

float getVoltage(int pin)
{
  return (analogRead(pin) * 0.004882814);

  // This equation converts the 0 to 1023 value that analogRead()
  // returns, into a 0.0 to 5.0 value that is the true voltage
  // being read at that pin.
}
```

```

Serial Monitor

# TMP36 Temperature Wiring

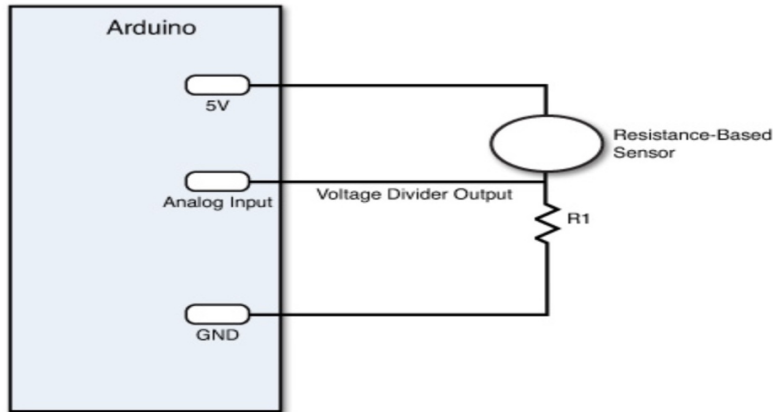

# Resistance-based Sensors

The problem with resistance sensors is that the Arduino analog interfaces can't directly detect resistance changes.

This will require some extra electronic components. The easiest way to detect a change in resistance is to convert that change to a voltage change. You do that using a **voltage divider**, as shown below.

## Thermistor

By keeping the power source output constant, as the resistance of the sensor changes, the voltage divider circuit changes, and the output voltage changes. The size of resistor you need for the R1 resistor depends on the resistance range generated by the sensor and how sensitive you want the output voltage to change.

E.g., the Steinhart-Hart Equation can be used to find the Temperature:

$$\frac{1}{T} = A + B \ln(R) + C(\ln(R))^3$$

Generally, a value between 1K and 10K ohms works just fine to create a meaningful output voltage that you can detect in your Arduino analog input interface.

# NTC Thermistor Example

```
// Read Temperature Values from NTC Thermistor
const int temperaturePin = 0;

void setup()
{
  Serial.begin(9600);
}

void loop()
{
  int temperature = getTemp();
  Serial.print("Temperature Value: ");
  Serial.print(temperature);
  Serial.println("*C");
  delay(1000);
}

double getTemp()
{
  // Inputs ADC Value from Thermistor and outputs Temperature in Celsius

  int RawADC = analogRead(temperaturePin);
  long Resistance;
  double Temp;

  // Assuming a 10k Thermistor. Calculation is actually: Resistance = (1024/ADC)
  Resistance=((1024000/RawADC) - 10000);

  // Utilizes the Steinhart-Hart Thermistor Equation:

  // Temperature in Kelvin = 1 / {A + B[ln(R)] + C[ln(R)]^3}
  // where A = 0.001129148, B = 0.000234125 and C = 8.76741E-08

  Temp = log(Resistance);
  Temp = 1 / (0.001129148 + (0.000234125 * Temp) + (0.0000000876741 * Temp * Temp * Temp));
  Temp = Temp - 273.15; // Convert Kelvin to Celsius
  return Temp; // Return the Temperature
}
```

The screenshot shows a Serial Monitor window titled "/dev/tty.usbmodem1421". The window displays a list of temperature readings: "Temperature Value: 24\*C" (repeated 7 times), "Temperature Value: 25\*C", "Temperature Value: 26\*C", "Temperature Value: 27\*C", "Temperature Value: 27\*C", "Temperature Value: 28\*C", and "Temperature Value: 27\*C". At the bottom of the window, there are settings: "Autoscroll" is checked, "No line ending" is selected, and "9600 baud" is set.

## Serial Monitor

## Steinhart-Hart Equation:

$$\frac{1}{T} = A + B \ln(R) + C(\ln(R))^3$$

Congratulations! - You are finished with the Task

# Pt-100 Measurements

Hans-Petter Halvorsen, M.Sc.

# Temperature Measurements

**Pt100:** Create your own temporary Pt-100 sensor with Transmitter (create the circuit on a breadboard) and then Read Temperature values using Arduino.

## Suggested Tasks:

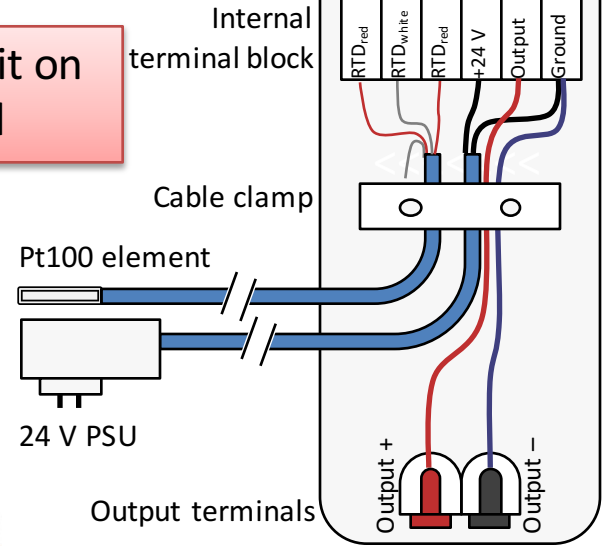

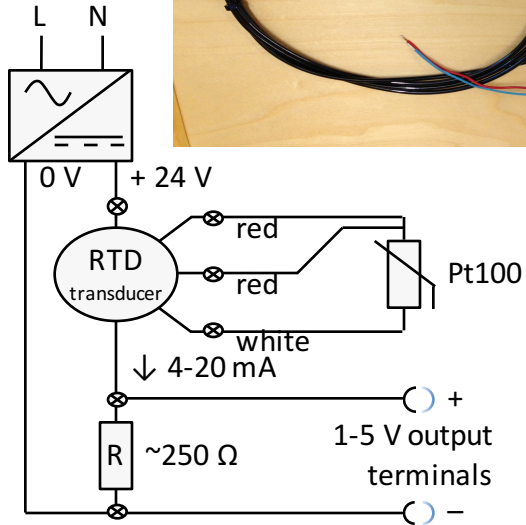

- Compare with Temperature Sensors available within the Arduino Kit (TMP36, Thermistor,...)
- Compare and Discuss the following Temperature Measurements; Pt-100, Thermocouple, Thermistor (Measurement principles, etc.)

# Pt-100 Wiring

This is a pre-made device.  
Your job is to create this using  
a Breadboard

Create this circuit on  
your breadboard

**Important!** Test the output of your circuit BEFORE connecting it to the Arduino Analog Input with a Multimeter to make sure the voltage is not higher than 5V, else the Arduino will be damaged!

# Create you own Pt-100 Sensor with Transmitter

Test the Device using Arduino

Temperature Transmitter (0-100deg. C)

# Important!

- Test the output of your circuit BEFORE connecting it to the Arduino Analog Input
- Use a Multimeter to make sure the voltage is not higher than 5V
- The Arduino will be damaged if the voltage is higher than 5V!

Congratulations! - You are finished with the Task

# Temperature Data Logger/ Embedded DAQ System

Hans-Petter Halvorsen, M.Sc.

# Temperature Data Logger/Embedded DAQ System

You use the PC when creating the software, then you download the software to the Arduino and disconnect the USB cable. Use e.g., a 9V battery or an external Power Supply.

NTC Thermistor

Use different Temperature sensors for comparison, i.e log data from 2 different sensors at the same time.

# Temperature Data Logger/ Embedded DAQ System

Create a **Temperature Logger/Embedded DAQ System**. Suggested Tasks:

- Create and use a **Lowpass Filter/Average Filter**
- **Alarm** functionality: Use LEDs with different colors when Temperature is above/below the Limits
- Use e.g., Arduino **Wi- Fi/Ethernet Shield** for Communication over a network - or use the microSD card on these Shields
- Save the data to a microSD card located on the Wi- Fi/Ethernet Shield - or connect e.g., to **xively.com** or **temboo.com** - which are free datalogging sites.
- Log Temperature Data for e.g., 24 hours and import Data into Excel, LabVIEW or MATLAB for Analysis and Visualization
- Use e.g. a 9V battery or an external power source to make it portable and small

# Arduino Wi-Fi/Ethernet Shield

<http://arduino.cc/en/Reference/WiFi>

With the Arduino Wi-Fi/Ethernet Shield, this library allows an Arduino board to connect to the internet. It can serve as either a server accepting incoming connections or a client making outgoing ones.

Arduino Wi-Fi Library: <http://arduino.cc/en/Reference/WiFi>

Arduino Ethernet Library: <http://arduino.cc/en/Reference/Ethernet>

SD Library: <http://arduino.cc/en/Reference/SD>

# Discrete Lowpass Filter

Lowpass Filter Transfer function:

$$H(s) = \frac{y(s)}{u(s)} = \frac{1}{T_f s + 1}$$

Inverse Laplace gives the differential Equation:

$$T_f \dot{y} + y = u$$

We use the Euler Backward method:

$$\dot{x} = \frac{x_k - x_{k-1}}{T_s}$$

This gives:

$$T_f \frac{y_k - y_{k-1}}{T_s} + y_k = u_k$$

$$y_k = \frac{T_f}{T_f + T_s} y_{k-1} + \frac{T_s}{T_f + T_s} u_k$$

Note! Implement the Lowpass Filter as a separate Function

We define:

$$\frac{T_s}{T_f + T_s} \equiv a$$

This gives:

$$y_k = (1 - a)y_{k-1} + au_k$$

Filter output

Noisy input signal

This algorithm can be easily implemented in a Programming language

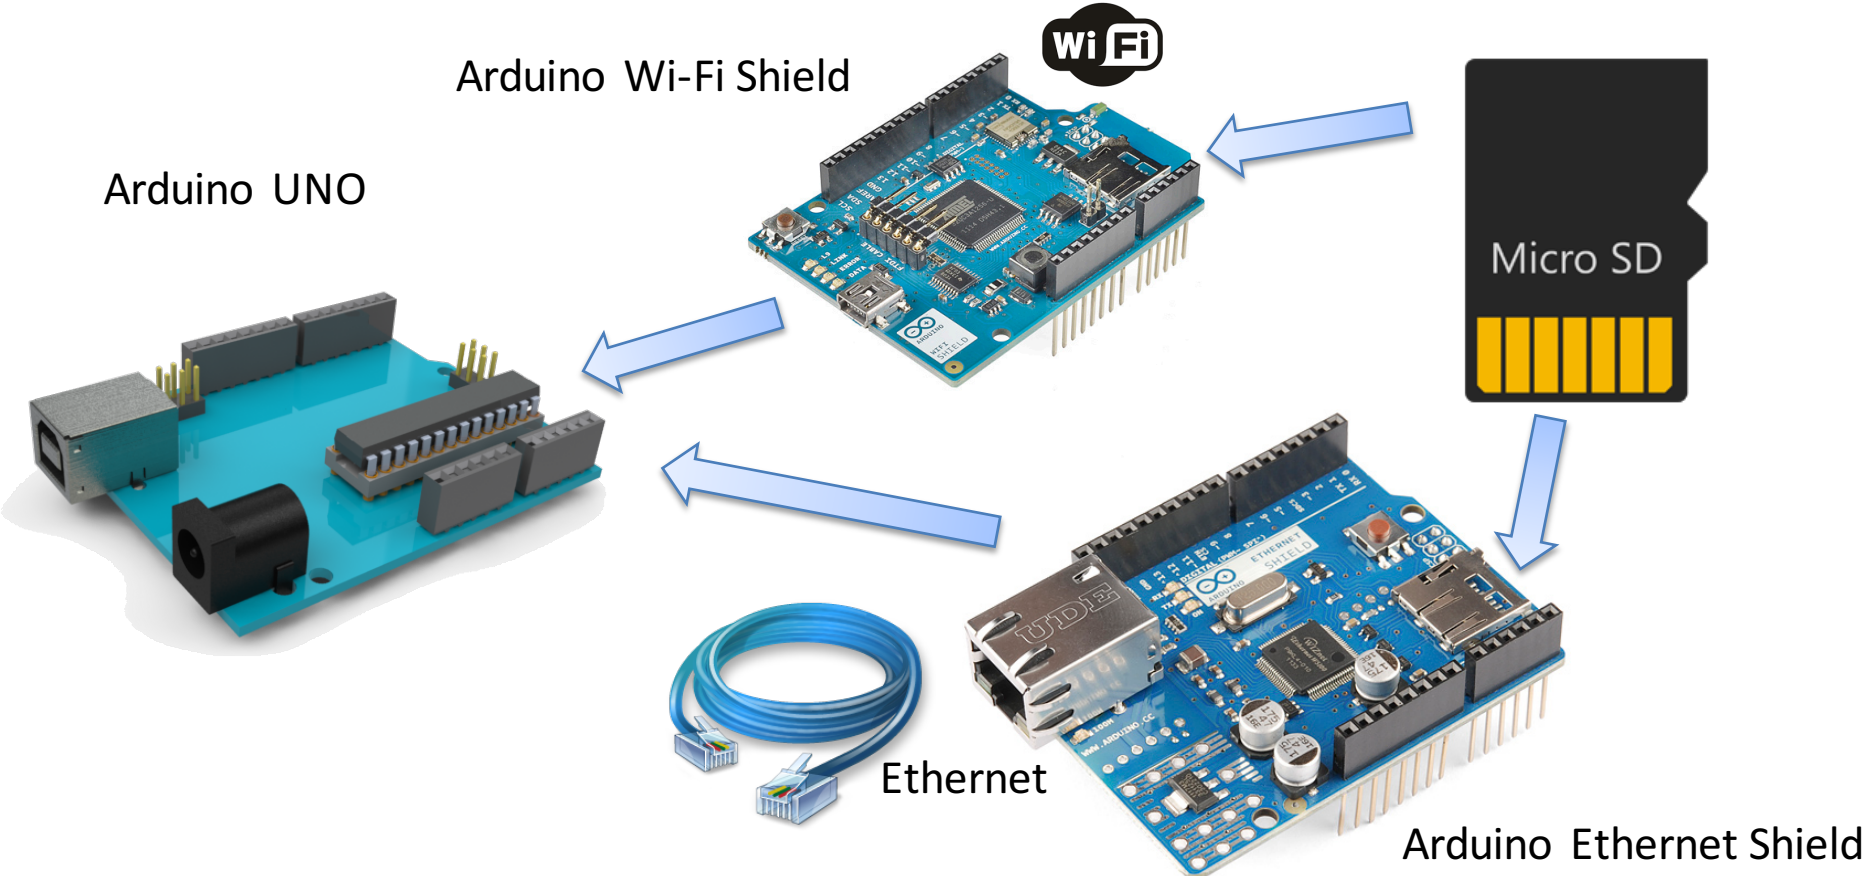

$$T_s \leq \frac{T_f}{5}$$

# Arduino Libraries

- The Arduino environment can be extended through the use of libraries, just like most programming platforms.
- Libraries provide extra functionality for use in sketches, e.g. working with hardware or manipulating data. A number of libraries come installed with the IDE, but you can also download or create your own.
- You could say an Arduino Library is like a Class with Methods/Functions. It is a good way to structure your code
- Examples:
  - Ethernet Library for the Arduino Ethernet Shield
  - SD Library: The SD library allows for reading from and writing to SD cards, e.g. on the Arduino Ethernet Shield or Arduino Wi-Fi Shield
  - Wi-Fi library for the Arduino Wi-Fi Shield
- Writing your own libraries: <https://www.arduino.cc/en/Hacking/LibraryTutorial>

# Arduino Ethernet/Wi-Fi Shield with SD Card

# Web-based Logging Service

You may want to connect e.g., to xively.com, a free datalogging site
