DEPARTMENT OF INFORMATION TECHNOLOGY

ITB201 – Design and Analysis of Algorithms

II YEAR IV SEM

UNIT 2 – Brute Force and Divide and Conquer

– Divide and Conquer-Multiplication of large Integers

Multiplying Two digit integers

$$\overbrace{\times 24} = 14 \overset{1}{\underline{5}} 2$$

$$\times 4 = 280$$

$$\times 3 = 60$$

$$\begin{array}{r} 22 \\ \times 43 \\ \hline 66 \\ 80 \end{array}$$

Multiplying Four digit integers

$$\begin{array}{r}
 \text{T} \quad \text{U} \\
 4 \quad 3 \\
 \hline
 1 \quad 2 \\
 \hline
 8 \quad 6 \quad \quad (43 \times 2) \\
 4 \quad 3 \quad 0 \quad \quad (43 \times 1) \\
 \hline
 86 \quad 16 \\
 \hline
 8616
 \end{array}$$

$$\begin{array}{r}
 \\
 \\
 \\
 \\
 \hline
 1 \quad 2 \quad 7 \quad 2 \\
 \hline
 5 \quad 0 \quad 8 \quad 8 \\
 \hline
 7 \quad 6 \quad 3 \quad 2 \quad 0 \\
 \\
 \\
 \\
 \\
 \\

 + \\
 \hline
 1 \quad 7 \quad 3 \quad 5 \quad 0 \quad 0 \quad 8
 \end{array}$$

er the problem of multiplying two n -digit integers represented by arrays of their digits such as $a = a_1a_2\dots$

de-school algorithm:

$$a_n \quad b_1 \quad b_2 \quad \dots \quad b_n$$

$$d_{12} \quad \dots \quad d_{1n}$$

$$d_{22} \quad \dots \quad d_{2n}$$

...

$$d_{n2} \quad \dots \quad d_{nn}$$

2-digit integers $a = 23$ and $b = 14$ can be expressed as follows:

$$23 = 2 \cdot 10^1 + 3 \cdot 10^0 \text{ and } 14 = 1 \cdot 10^1 + 4 \cdot 10^0.$$

Thus multiply them:

$$(2 \cdot 10^1 + 3 \cdot 10^0) * (1 \cdot 10^1 + 4 \cdot 10^0)$$

$$= 2 \cdot 10^2 + (2 * 4 + 3 * 1)10^1 + (3 * 4)10^0$$

ula uses four digit multiplications (i.e., n^2).

erm can be computed by

$$1 = (2 + 3) * (1 + 4) - 2 * 1 - 3 * 4.$$

any multiplications? 1 or 3

-digit integers $a = a_1a_0$ and $b = b_1b_0$, then

can be computed by

$$c_210^2 + c_110^1 + c_0,$$

is the product of their first digits,

b_0 is the product of their second digits,
 $(a_2 + a_0) * (b_1 + b_0) - (c_2 + c_0)$ is the product
of the a 's digits and the sum of the b 's digits
minus the sum of c_2 and c_0 .

eral, for two n -digit integers a and b where n is an even number. We denote the first half of a by a_1 and the second half by a_0 ; for b , the notation is b_1 and b_0 , respectively. In these notations, $a = a_1 \cdot 10^{n/2} + a_0$ and $b = b_1 \cdot 10^{n/2} + b_0$.

Example: $a = 21 \mid 35$, $b = 40 \mid 14$

$$\begin{aligned}
 &= (a_1 10^{n/2} + a_0) * (b_1 10^{n/2} + b_0) \\
 &= (a_1 * b_1) 10^n + (a_1 * b_0 + a_0 * b_1) 10^{n/2} + (a_0 * b_0) \\
 &= c_1 10^{n/2} + c_0, \text{ where}
 \end{aligned}$$

c_1 is the product of their first halves,

and Conquer Algorithm

* b_0 is the product of their second halves,

$(a_1 + a_0) * (b_1 + b_0) - (c_2 + c_0)$ is the product of the sum of the a 's halves and the sum of the b 's halves minus the sum of the c 's halves minus c_0 .

Instead of using 4 multiplications to compute $a * b$, we just need to compute 3

multiplications (i.e., $a_1 * b_1$, $(a_0 * b_0)$, and $(a_1 + a_0) * (b_1 + b_0)$).

Divide and Conquer Algorithm

Apply the same method for computing the product of two integers. We have recursive algorithm for computing product of two integers. The recursion is stopped when n becomes one.

Apply the same method for computing the product of two integers. We have recursive algorithm for computing product of two integers. The recursion is stopped when n becomes one.

Divide and Conquer Algorithm

Multiplication of n -digit numbers requires three multiplications of $n/2$ -digit numbers, the recurrence for the number of multiplications $M(n)$ will be

$$M(n) = 3M(n/2) \text{ for } n > 1, M(1) = 1.$$

and Conquer Algorithm

g it by backward substitutions for $n =$

$$= 3M(2^{k-1}) = 3[3M(2^{k-2})] = 3^2M(2^{k-2})$$

$$3^iM(2^{k-i}) = \dots = 3^kM(2^{k-k}) = 3^k.$$

$$k = \log_2 n,$$

$$M(n) = 3^{\log_2 n} = n^{\log_2 3} \approx n^{1.585} < n^2.$$

Can the running time of multiplication of large integers be conquered?

Integer multiplication can't be solved by using brute force.

Thank You
