

SNS COLLEGE OF TECHNOLOGY

Coimbatore-35
An Autonomous Institution

Accredited by NBA – AICTE and Accredited by NAAC – UGC with 'A+' Grade
Approved by AICTE, New Delhi & Affiliated to Anna University, Chennai

DEPARTMENT OF INFORMATION TECHNOLOGY

WEB TECHNOLOGY

III YEAR - V SEM

UNIT 1 – Web Site Basics And HTML

TOPIC 4 - HTTP request/response Message

Hypertext Transfer Protocol (HTTP)

- ▶ HTTP is based on the **request-response** communication model:
 - ▶ Client sends a request
 - ▶ Server sends a response
- ▶ HTTP is a **stateless** protocol:
 - ▶ The protocol does not require the server to remember anything about the client between requests.

HTTP

- ▶ Normally implemented over a TCP connection (80 is standard port number for HTTP)
- ▶ Typical browser-server interaction:
 - ▶ User enters Web address in browser
 - ▶ Browser uses DNS to locate IP address
 - ▶ Browser opens TCP connection to server
 - ▶ Browser sends HTTP request over connection
 - ▶ Server sends HTTP response to browser over connection
 - ▶ Browser displays body of response in the **client area** of the browser window

HTTP

- ▶ The information transmitted using HTTP is often entirely text
- ▶ Can use the Internet's **Telnet** protocol to simulate browser request and view server response

HTTP

```
Connect { $ telnet www.example.org 80
          Trying 192.0.34.166...
          Connected to www.example.com (192.0.34.166).
          Escape character is '^]'.
          GET / HTTP/1.1
          Host: www.example.org

Send Request { HTTP/1.1 200 OK
               Date: Thu, 09 Oct 2020 20:30:49 GMT
               ...

Receive Response {
```

HTTP Request

- ▶ Structure of the request:
 - ▶ start line
 - ▶ header field(s)
 - ▶ blank line
 - ▶ optional body

HTTP Request

- ▶ Structure of the request:
 - ▶ start line
 - ▶ header field(s)
 - ▶ blank line
 - ▶ optional body

HTTP Request

- ▶ Start line
 - ▶ Example: GET / HTTP/1.1
- ▶ Three space-separated parts:
 - ▶ HTTP request method
 - ▶ Request-URI (**Uniform Resource Identifier**)
 - ▶ HTTP version

HTTP Request

- ▶ Start line
 - ▶ Example: GET / HTTP/1.1
- ▶ Three space-separated parts:
 - ▶ HTTP request method
 - ▶ Request-URI
 - ▶ HTTP version

HTTP Request

- ▶ **Uniform Resource Identifier (URI)**
 - ▶ Syntax: *scheme : scheme-depend-part*
 - ▶ Ex: In <http://www.example.com/> the **scheme** is http
 - ▶ **Request-URI** is the portion of the requested URI that follows the host name (which is supplied by the required Host header field)
 - ▶ Ex: / is Request-URI portion of <http://www.example.com/>

URI

- ▶ URI's are of two types:
 - ▶ Uniform Resource Name (URN)
 - ▶ Can be used to identify resources with unique names, such as books (which have unique ISBN's)
 - ▶ Scheme is urn
 - ▶ Uniform Resource Locator (URL)
 - ▶ Specifies location at which a resource can be found
 - ▶ In addition to http, some other URL schemes are https, ftp, mailto, and file

HTTP Request

- ▶ Start line
 - ▶ Example: GET / HTTP/1.1
- ▶ Three space-separated parts:
 - ▶ HTTP request method
 - ▶ Request-URI
 - ▶ HTTP version

HTTP Request

- ▶ Common request methods:
 - ▶ GET
 - ▶ Used if link is clicked or address typed in browser
 - ▶ No body in request with GET method
 - ▶ POST
 - ▶ Used when submit button is clicked on a form
 - ▶ Form information contained in body of request
 - ▶ HEAD
 - ▶ Requests that only header fields (no body) be returned in the response

HTTP Request

- ▶ Structure of the request:
 - ▶ start line
 - ▶ header field(s)
 - ▶ blank line
 - ▶ optional body

HTTP Request

- ▶ Header field structure:
 - ▶ *field name* : *field value*
- ▶ Syntax
 - ▶ **Field name** is not case sensitive
 - ▶ **Field value** may continue on multiple lines by starting continuation lines with white space
 - ▶ Field values may contain **MIME types**, **quality values**, and **wildcard characters** (*'s)

Multipurpose Internet Mail Extensions (MIME)

- ▶ Convention for specifying **content type** of a message
 - ▶ In HTTP, typically used to specify content type of the body of the response
- ▶ MIME content type syntax:
 - ▶ *top-level type / subtype*
- ▶ Examples: text/html, image/jpeg

HTTP Quality Values and Wildcards

- ▶ Example header field with **quality values**:
accept:
`text/xml, text/html; q=0.9,
text/plain; q=0.8, image/jpeg,
image/gif; q=0.2, */*; q=0.1`
- ▶ Quality value applies to all preceding items
- ▶ Higher the value, higher the preference
- ▶ Note use of wildcards to specify quality 0.1 for any MIME type not specified earlier

HTTP Request

- ▶ **Common header fields:**
 - ▶ **Host:** host name from URL (required)
 - ▶ **User-Agent:** type of browser sending request
 - ▶ **Accept:** MIME types of acceptable documents
 - ▶ **Connection:** value `close` tells server to close connection after single request/response
 - ▶ **Content-Type:** MIME type of (POST) body, normally `application/x-www-form-urlencoded`
 - ▶ **Content-Length:** bytes in body
 - ▶ **Referer:** URL of document containing link that supplied URI for this HTTP request

HTTP Response

- ▶ Structure of the response:
 - ▶ status line
 - ▶ header field(s)
 - ▶ blank line
 - ▶ optional body

HTTP Response

- ▶ Structure of the response:
 - ▶ status line
 - ▶ header field(s)
 - ▶ blank line
 - ▶ optional body

HTTP Response

- ▶ Status line
 - ▶ Example: HTTP/1.1 200 OK
- ▶ Three space-separated parts:
 - ▶ HTTP version
 - ▶ status code
 - ▶ reason phrase (intended for human use)

HTTP Response

- ▶ **Status** code
 - ▶ Three-digit number
 - ▶ First digit is class of the status code:
 - ▶ 1=Informational
 - ▶ 2=Success
 - ▶ 3=Redirection (alternate URL is supplied)
 - ▶ 4=Client Error
 - ▶ 5=Server Error
 - ▶ Other two digits provide additional information
 - ▶ See <http://www.w3.org/Protocols/rfc2616/rfc2616-sec10.html>

HTTP Response

- ▶ Structure of the response:
 - ▶ status line
 - ▶ **header field(s)**
 - ▶ blank line
 - ▶ optional body

HTTP Response

- ▶ Common header fields:
 - ▶ **Connection**, **Content-Type**, **Content-Length**
 - ▶ **Date**: date and time at which response was generated (required)
 - ▶ **Location**: alternate URI if status is redirection
 - ▶ **Last-Modified**: date and time the requested resource was last modified on the server
 - ▶ **Expires**: date and time after which the client's copy of the resource will be out-of-date
 - ▶ **ETag**: a unique identifier for this version of the requested resource (changes if resource changes)

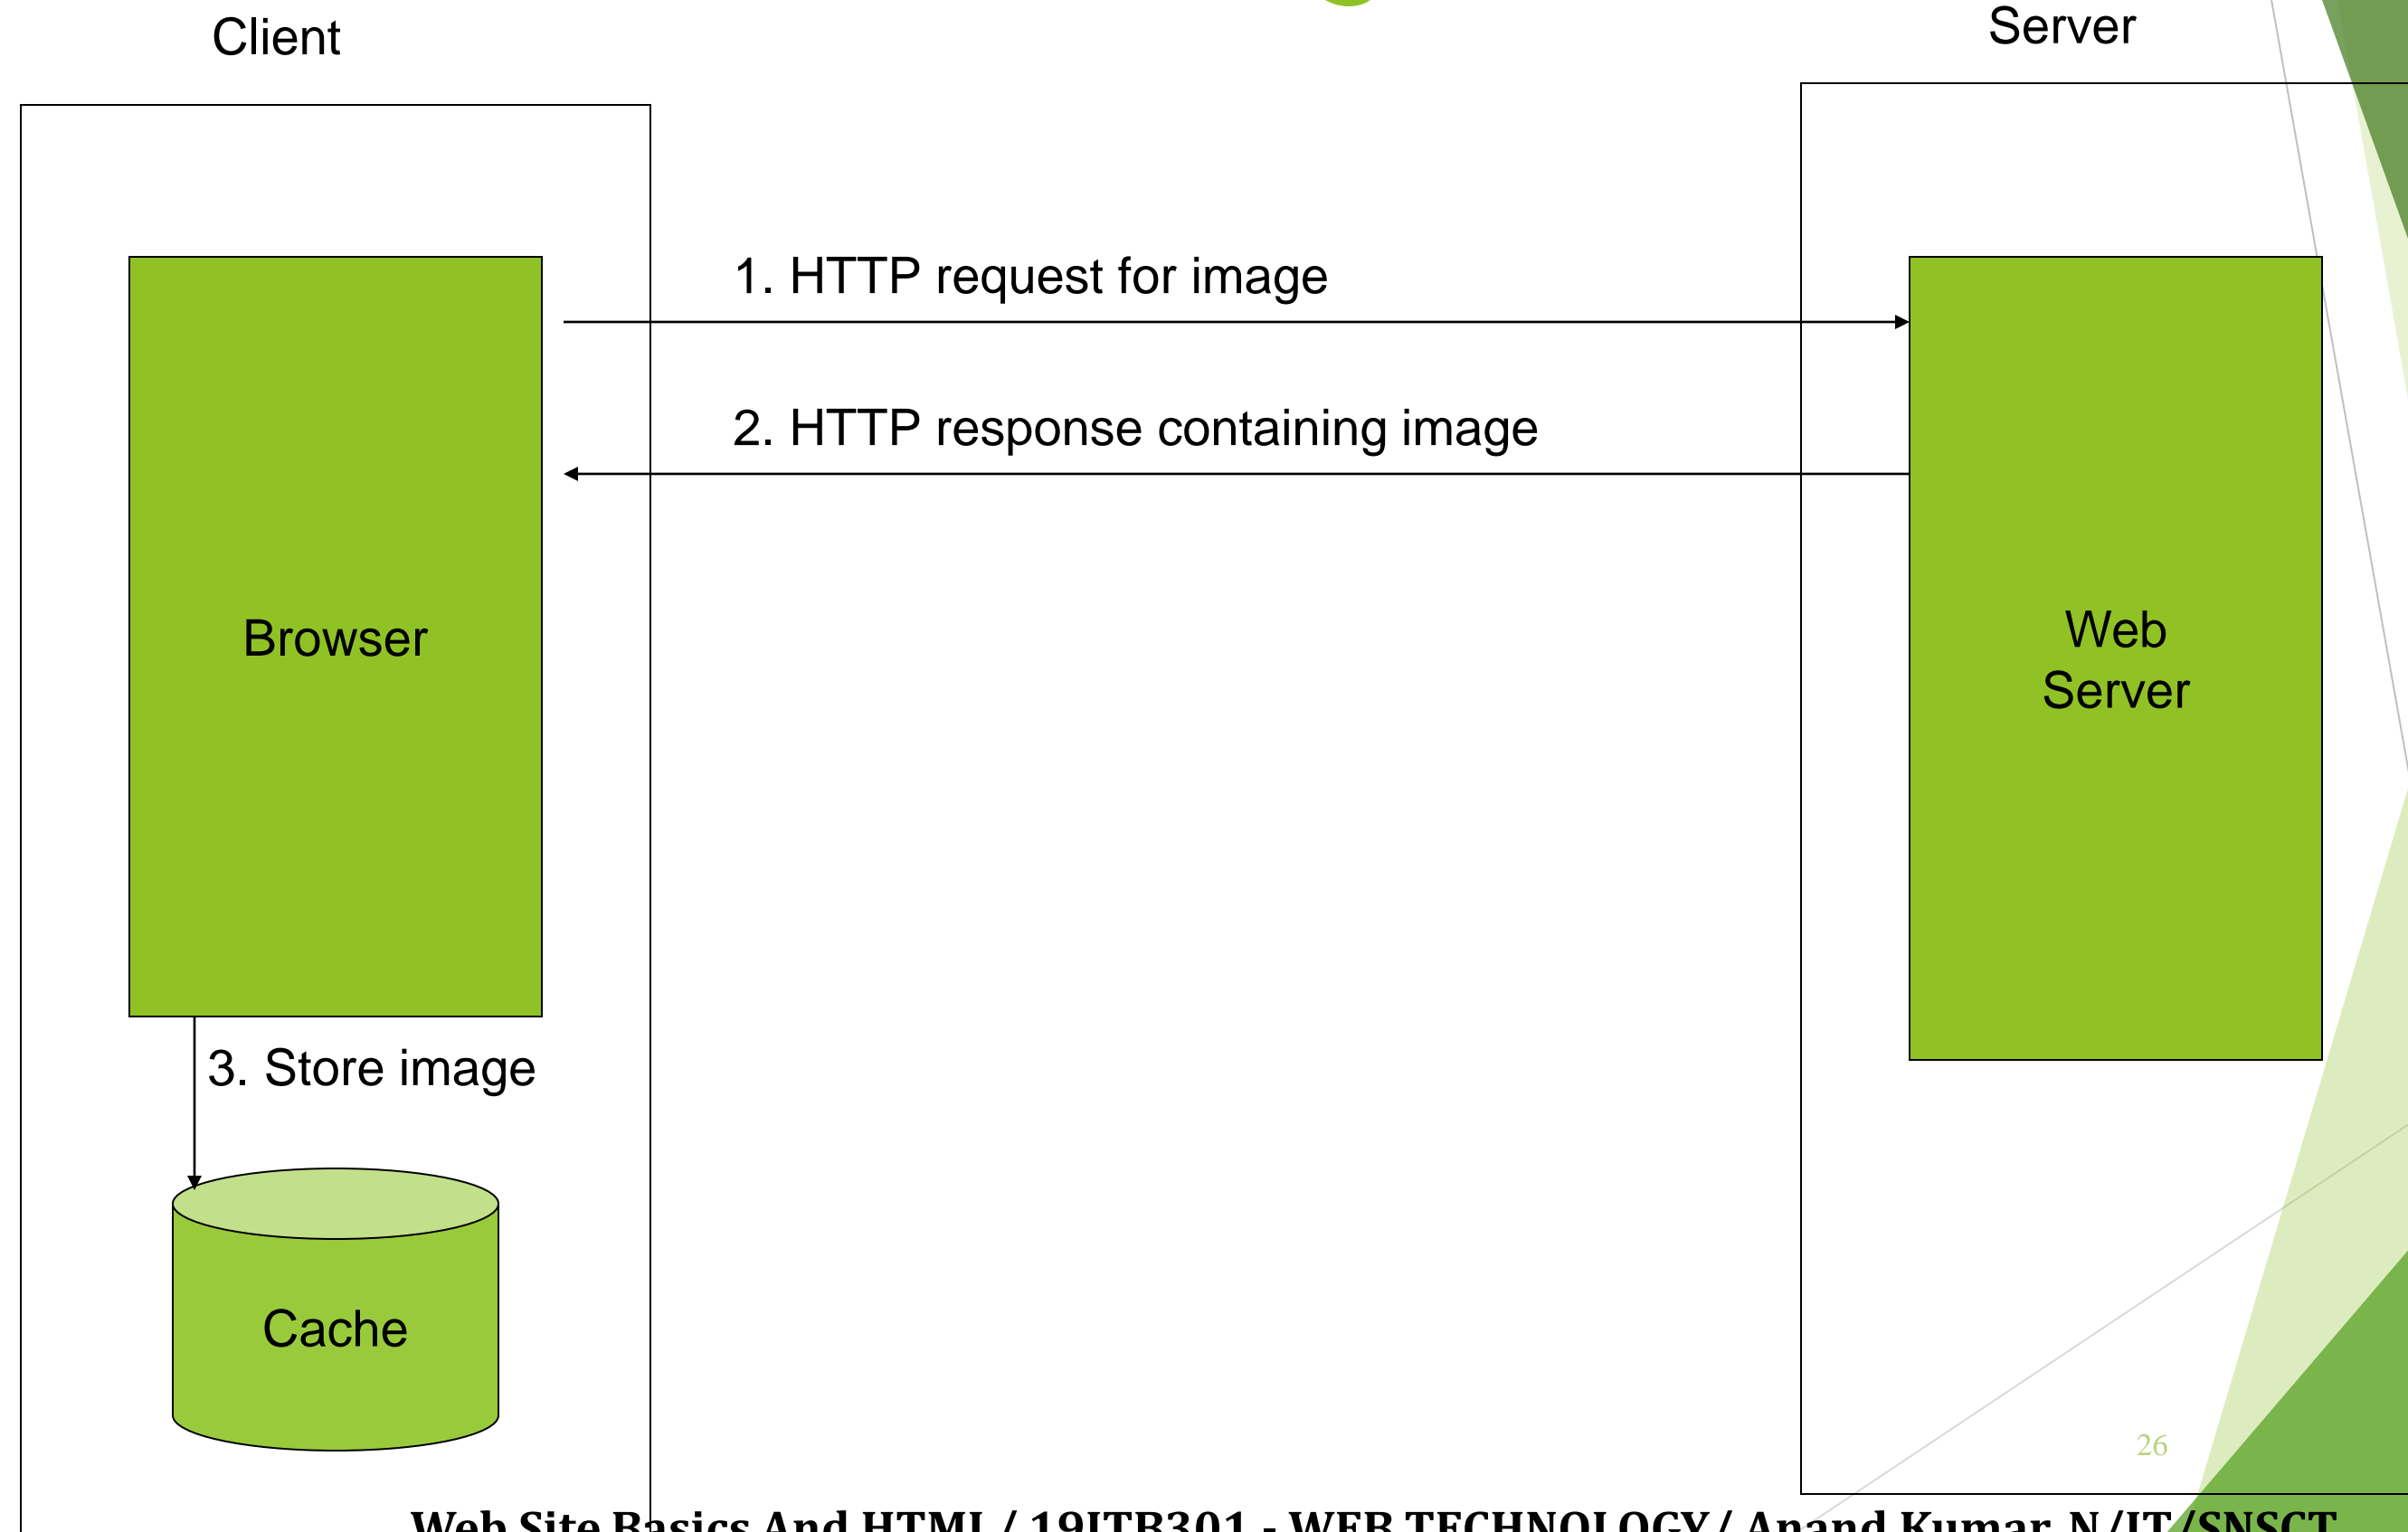

Client Caching

- ▶ A **cache** is a local copy of information obtained from some other source
- ▶ Most web browsers use cache to store requested resources so that subsequent requests to the same resource will not necessarily require an HTTP request/response
 - ▶ Ex: icon appearing multiple times in a Web page

Client Caching

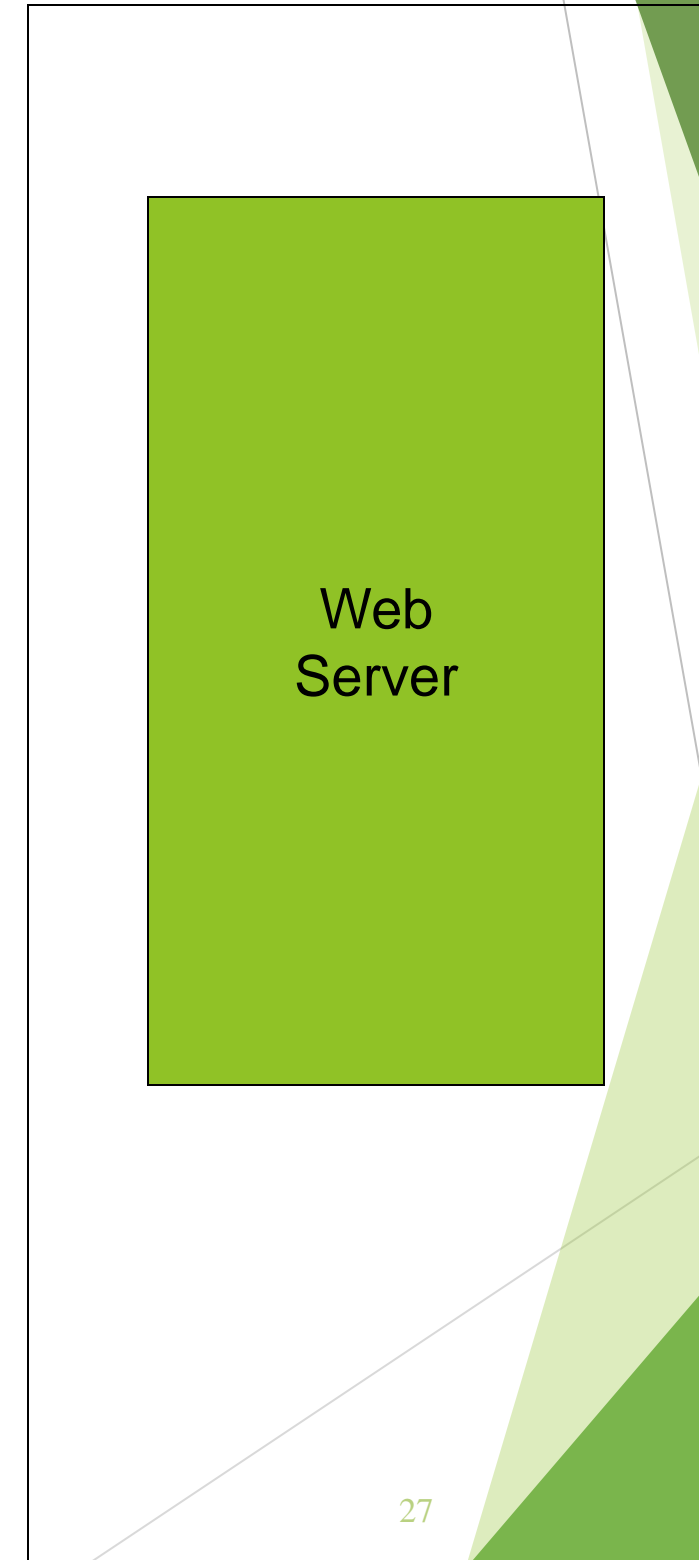

Client Caching

Client

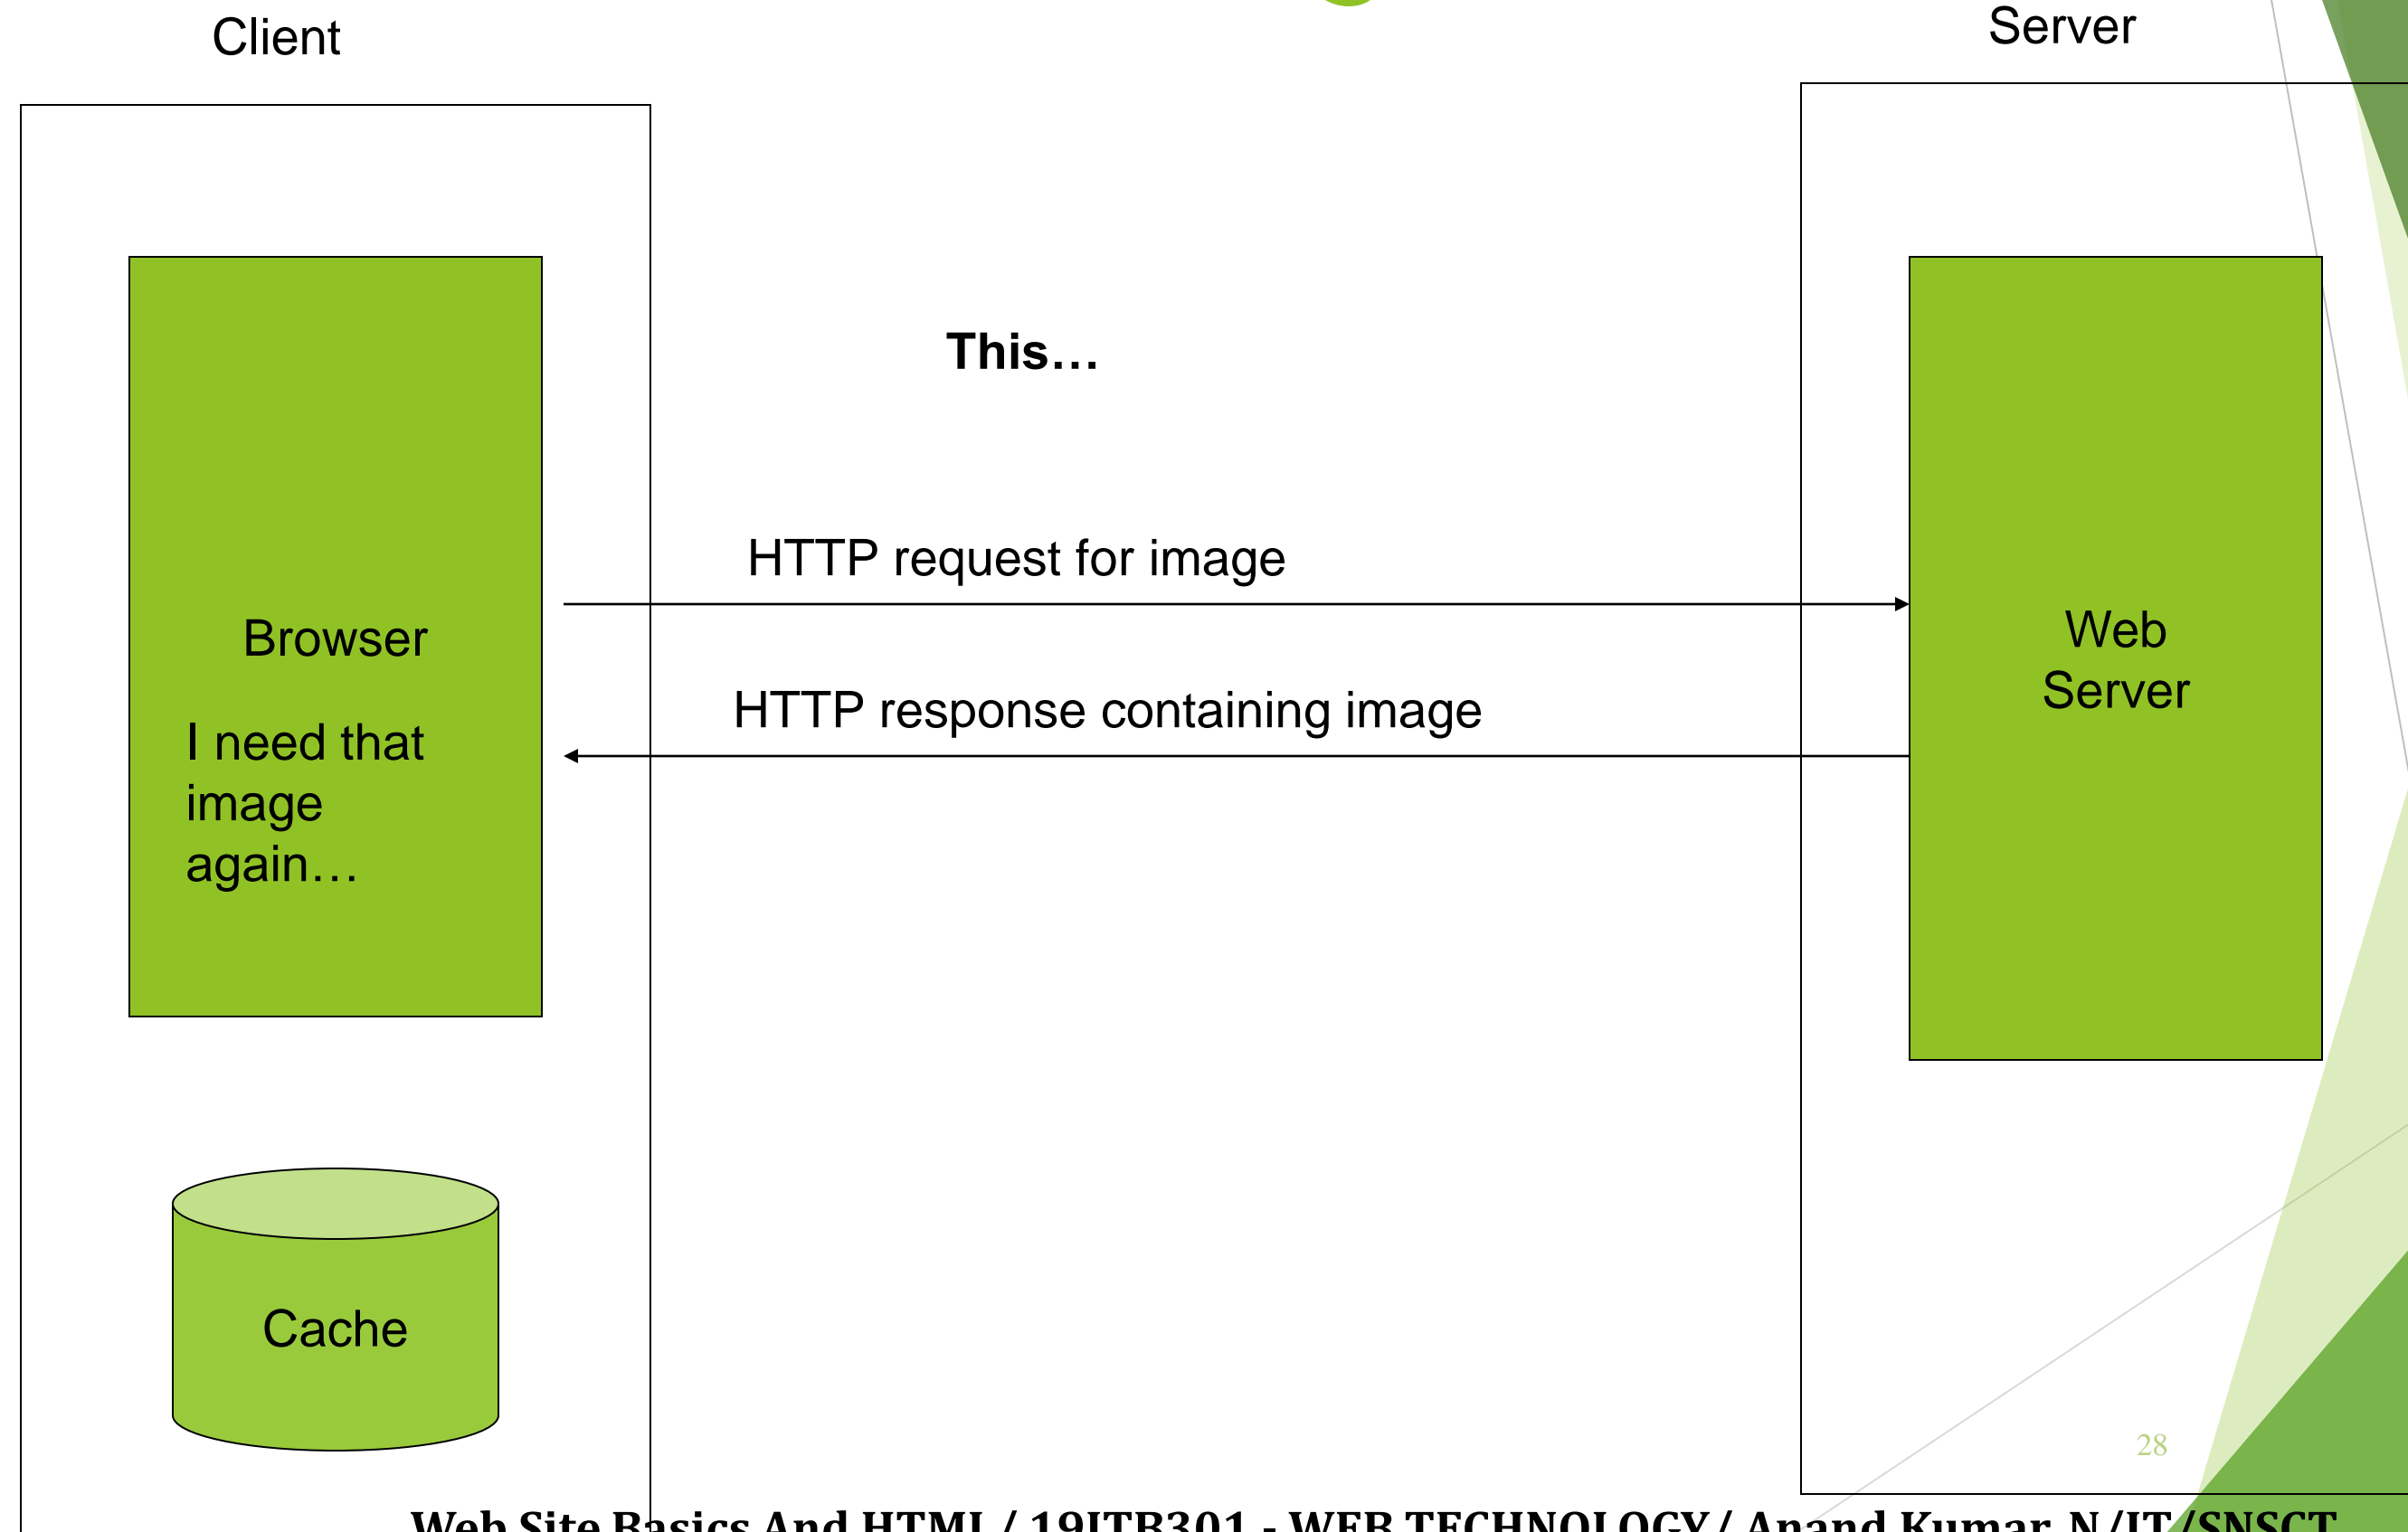

Server

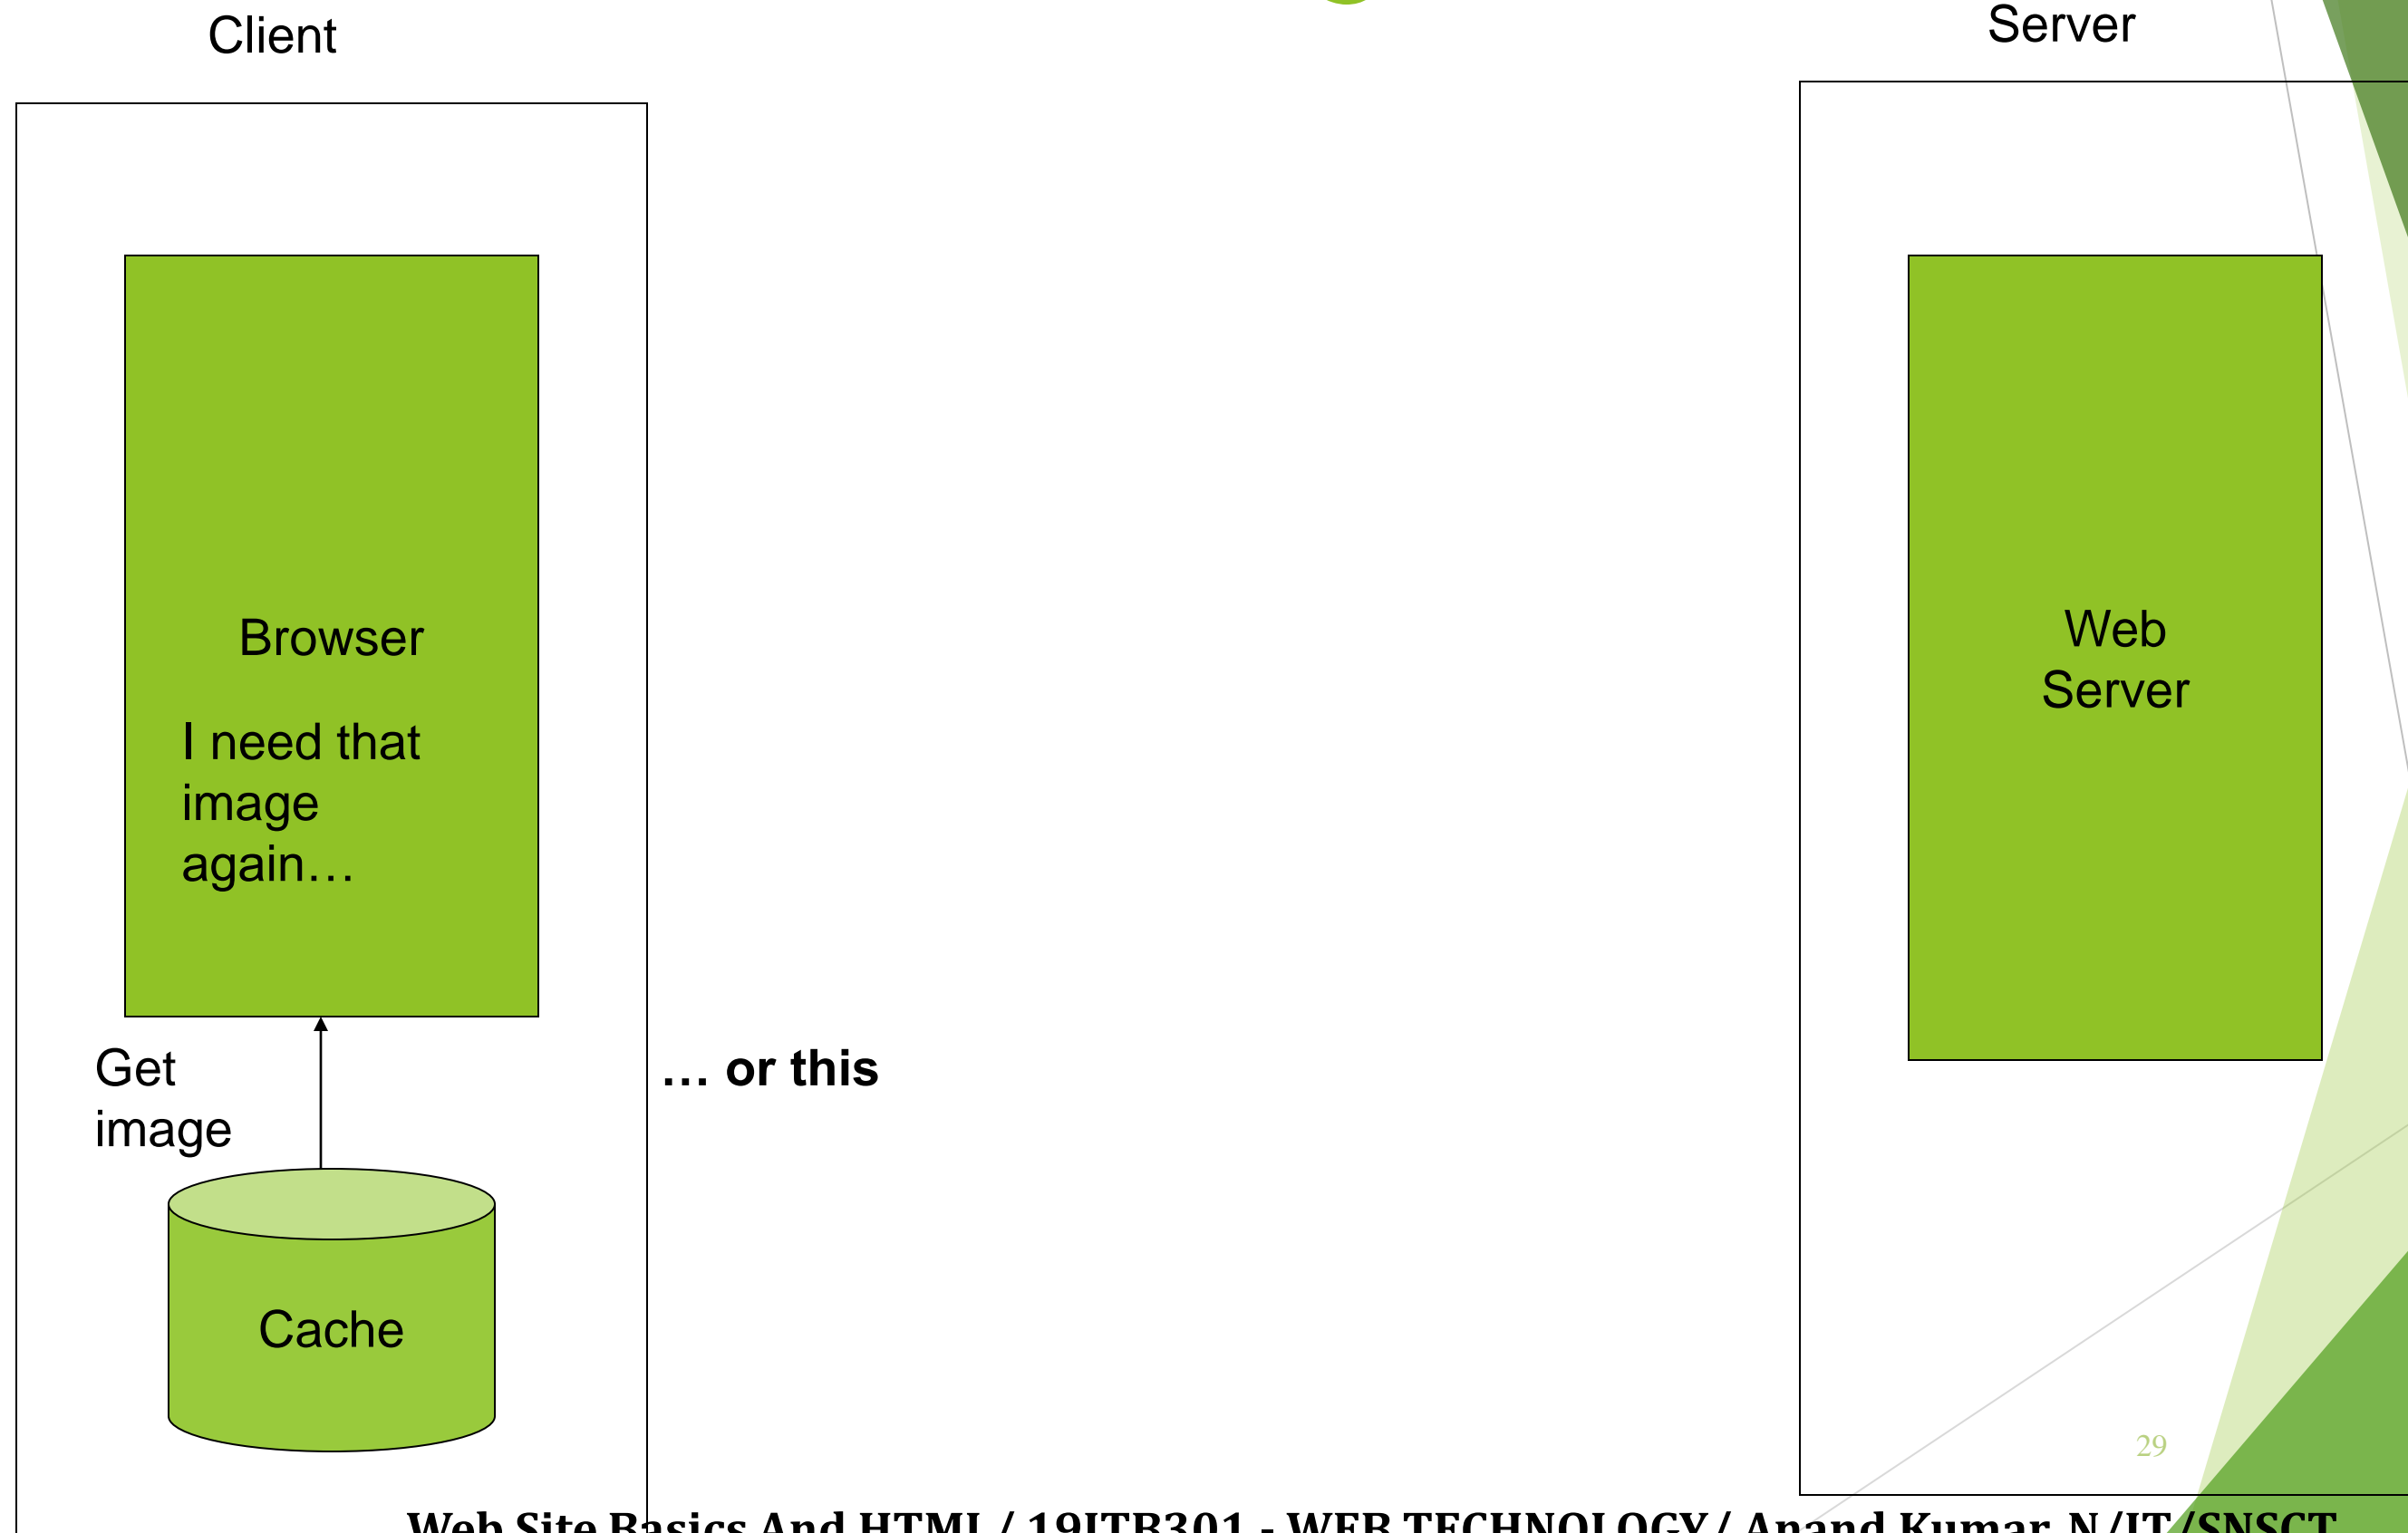

Client Caching

Client Caching

Client Caching

- ▶ Cache advantages
 - ▶ (Much) faster than HTTP request/response
 - ▶ Less network traffic
 - ▶ Less load on server
- ▶ Cache disadvantage
 - ▶ Cached copy of resource may be **invalid** (inconsistent with remote version)

Client Caching

- ▶ Validating cached resource:
 - ▶ Send HTTP HEAD request and check Last-Modified or ETag header in response
 - ▶ Compare current date/time with Expires header sent in response containing resource
 - ▶ If no Expires header was sent, use heuristic algorithm to estimate value for Expires
 - ▶ Ex: Expires = 0.01 * (Date - Last-Modified) + Date

Character Sets

- ▶ Every document is represented by a string of integer values (**code points**)
- ▶ The mapping from code points to characters is defined by a **character set**
- ▶ Some header fields have character set values:
 - ▶ **Accept-Charset**: request header listing character sets that the client can recognize
 - ▶ Ex: accept-charset: ISO-8859-1,utf-8;q=0.7,*;q=0.5
 - ▶ **Content-Type**: can include character set used to represent the body of the HTTP message
 - ▶ Ex: Content-Type: text/html; charset=UTF-8

Character Sets

- ▶ Technically, many “character sets” are actually **character encodings**
 - ▶ An encoding represents code points using **variable-length** byte strings
 - ▶ Most common examples are Unicode-based encodings UTF-8 and UTF-16
- ▶ IANA maintains [complete list](#) of Internet-recognized character sets/encodings

Character Sets

- ▶ Typical US PC produces ASCII documents
- ▶ **US-ASCII** character set can be used for such documents, but is not recommended
- ▶ UTF-8 and ISO-8859-1 are supersets of US-ASCII and provide international compatibility
 - ▶ **UTF-8** can represent all ASCII characters using a single byte each and arbitrary Unicode characters using up to 4 bytes each
 - ▶ **ISO-8859-1** is 1-byte code that has many characters common in Western European languages, such as é
