Approved by AICTE, New Delhi & Affiliated to Anna University, Chennai

DEPARTMENT OF AIML

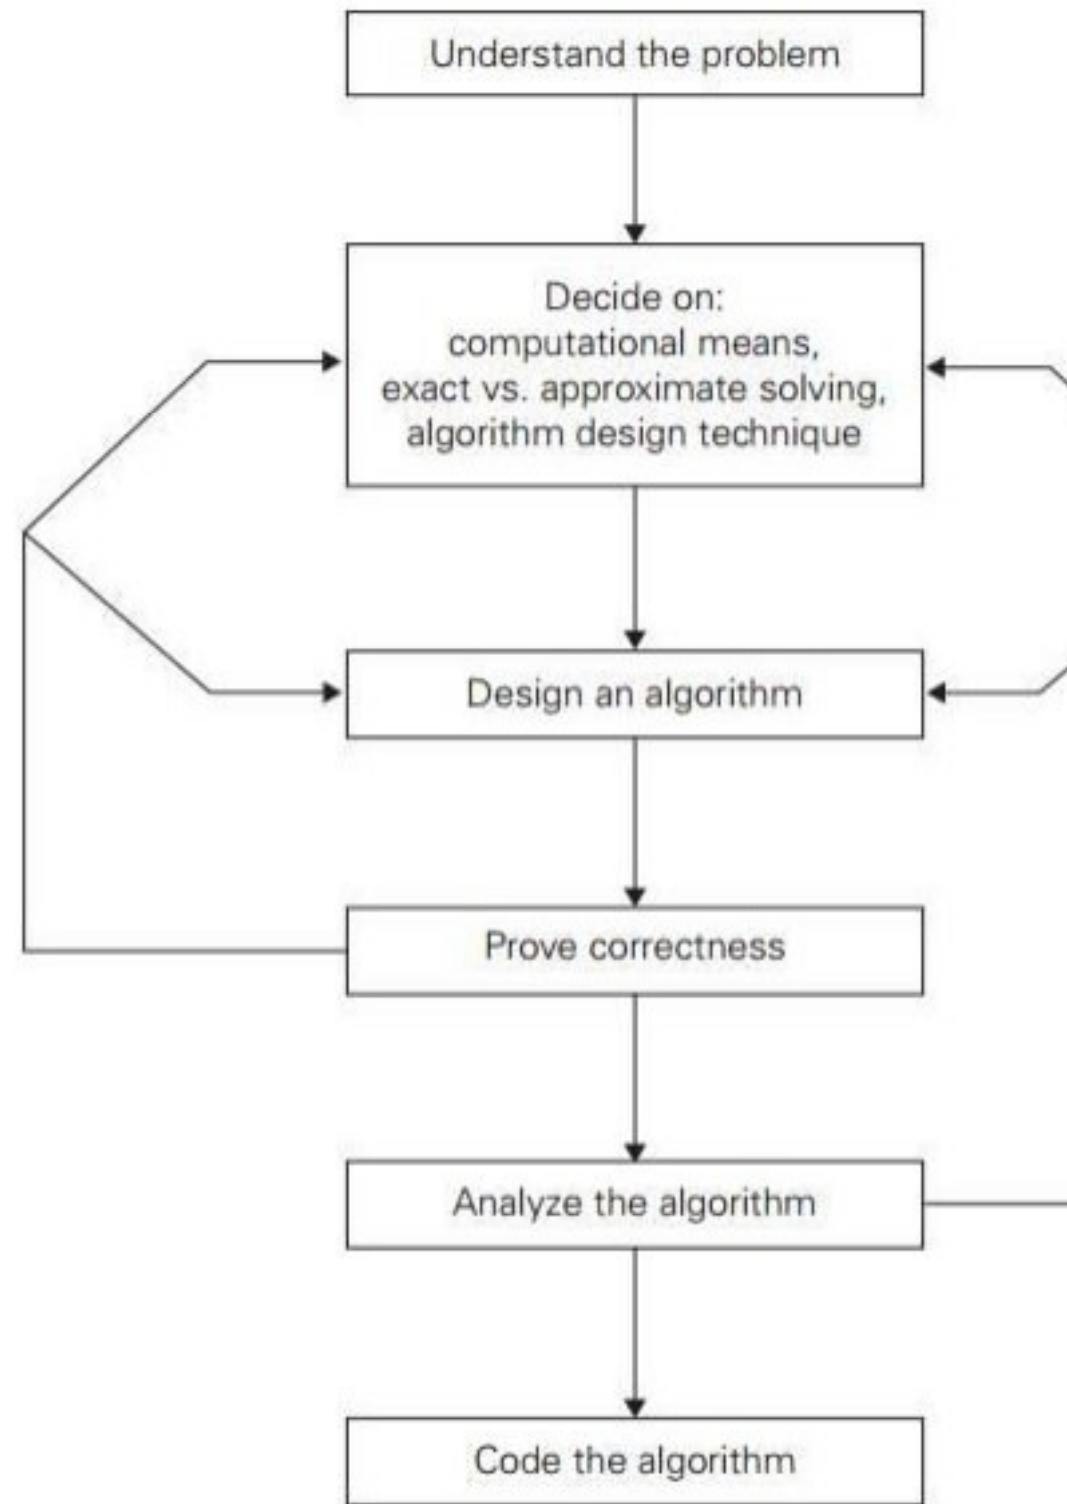

PROBLEM SOLVING AND C PROGRAMMING

I YEAR - I SEM

Unit 1 – Introduction to Problem Solving Techniques

TOPIC 5 – Algorithmic Problem Solving

Algorithmic problem solving is solving
problems that require the formulation
of an algorithm for the solution.

process of **finding the input** of the problem that the algorithm

is important to specify **exactly the set of inputs** the algorithm

The algorithm is not one that works most of the time, but
for all legitimate inputs.

Understanding the Capabilities of the Computational Device:

If instructions are executed one after another, it is called **sequential**

If instructions are executed concurrently, it is called **parallel**

PROBLEM SOLVING

principal decision is to choose between solving the problem **exactly** or **approximately**.

Thus, the algorithms are classified as **exact** algorithm and **approximate** algorithm.

data structure:

data structure plays a vital role in designing and analysis the algorithm. The choice of the algorithm design techniques also depend on the nature of the problem and the size of the problem's instance.

Algorithm + Data structure = programs.

Algorithm design technique (or “strategy” or “paradigm”) is a general method for solving a wide range of problems algorithmically that is applicable to a variety of different areas of computing.

The study of these techniques is of utmost importance for the following reasons:

1. They provide guidance for designing algorithms for new problems.

2. Algorithms are the cornerstone of computer science.

e:

docode is a mixture of a natural language and programming language constructs.

docode is usually more precise than natural language, and its usage is the key to the success in algorithm descriptions.

In the earlier days of computing, the dominant vehicle for specifying an algorithm was a flowchart, a method of expressing an algorithm by a collection of connected boxes containing descriptions of the algorithm's steps.

Programming language:

A programming language can be fed into an electronic computer directly. However, in most cases, it needs to be converted into a computer program written in a machine language.

We can look at such a program as yet another way of specifying the algorithm. It is often preferable to consider it as the algorithm's implementation.

Algorithm has been specified, you have to prove its correctness.

You have to prove that the algorithm **yields a required result for every finite amount of time.**

One technique for proving correctness is to use **mathematical induction**. Iterations provide a natural sequence of steps needed for such proof.

It is worth mentioning that although tracing the algorithm's performance on various inputs can be a very worthwhile activity, it cannot prove the algorithm correct.

To show that an algorithm is incorrect, you need just one instance where the algorithm fails.

algorithms are destined to be ultimately implemented as
.

Timing an algorithm presents both a peril and an opportunity.

Timing program provides an additional opportunity in all
analysis (Pattern and Observations) of the underlying algo

analysis is based on timing the program on several inputs
; the results obtained.

ey.

fficiency:

ating how fast the algorithm runs.

efficiency:

ating how much extra memory it uses.

ey.

orithm should be precisely defined and investigated with
natical expressions.

er algorithms are easier to understand and easier to program

e algorithms usually contain fewer bugs.
